

# **RSTS/E RMS-11 Macro Programmer's Guide**

Order No. AA-P507A-TC

**March 1983**

This document is a reference manual describing the macros and symbols that make up the interface between a MACRO-11 program and the operation routines of Record Management Services for PDP-11 operating systems (RMS-11).

<b>SUPERSESSION/UPDATE INFORMATION:</b>	This revised document supersedes the RMS-11 MACRO-11 Reference Manual (Order No. AA-H683A-TC) for RSTS/E users.
<b>OPERATING SYSTEM AND VERSION:</b>	RSTS/E Version 8.0
<b>SOFTWARE VERSION:</b>	RMS-11 Version 2.0

#### HOW TO ORDER ADDITIONAL DOCUMENTATION

In Continental USA and Puerto Rico call 800-258-1710  
In New Hampshire, Alaska, and Hawaii call 603-884-6660  
In Canada call 613-234-7726 (Ottawa-Hull)  
800-267-6146 (all other Canadian)

##### DIRECT MAIL ORDERS (USA & PUERTO RICO)\*

Digital Equipment Corporation  
P.O. Box CS2008  
Nashua, New Hampshire 03061

\*Any prepaid order from Puerto Rico must be placed  
with the local Digital subsidiary (809-754-7575)

##### DIRECT MAIL ORDERS (CANADA)

Digital Equipment of Canada Ltd.  
940 Belfast Road  
Ottawa, Ontario K1G 4C2  
Attn: A&SG Business Manager

##### DIRECT MAIL ORDERS (INTERNATIONAL)

Digital Equipment Corporation  
A&SG Business Manager  
c/o Digital's local subsidiary or  
approved distributor

---

Internal orders should be placed through the Software Distribution Center (SDC), Digital Equipment Corporation, Northboro, Massachusetts 01532

---

## CONTENTS

PREFACE		xi
SUMMARY OF TECHNICAL CHANGES		xv
CHAPTER 1	INTRODUCTION TO RMS-11 WITH MACRO-11	
1.1	ADVANTAGES OF USING RMS-11 MACROS . . . . .	1-1
1.2	RMS-11 MACROS AND SYMBOLS . . . . .	1-1
1.2.1	Operations . . . . .	1-2
1.2.2	Control Blocks and Fields . . . . .	1-2
1.2.3	Pools . . . . .	1-3
1.2.4	Facilities . . . . .	1-3
1.2.5	Macros That Declare Symbols and Other Macros . .	1-3
CHAPTER 2	RMS-11 PROGRAMMING	
2.1	DECLARING RMS-11 MACROS AND SYMBOLS . . . . .	2-2
2.2	DECLARING RMS-11 FACILITIES . . . . .	2-2
2.3	DECLARING AND USING POOL SPACE . . . . .	2-4
2.3.1	Internal FAB and Index Descriptor Block Pool . .	2-5
2.3.2	Internal RAB Pool . . . . .	2-5
2.3.3	Key Buffer Pool . . . . .	2-6
2.3.4	I/O Buffer Pool . . . . .	2-6
2.3.5	Buffer Descriptor Block Pool . . . . .	2-8
2.4	DECLARING AND INITIALIZING CONTROL BLOCKS . . . .	2-8
2.5	USING RMS-11 OPERATIONS . . . . .	2-9
2.5.1	Setting Up Control Block Fields . . . . .	2-10
2.5.1.1	\$STORE Macro . . . . .	2-10
2.5.1.2	\$SET Macro . . . . .	2-11
2.5.1.3	\$OFF Macro . . . . .	2-11
2.5.2	Chaining Control Blocks . . . . .	2-12
2.5.2.1	Chaining a NAM Block to a FAB . . . . .	2-12
2.5.2.2	Chaining XABs to a FAB . . . . .	2-12
2.5.2.3	Chaining a FAB to a RAB (CONNECT Operation) .	2-13
2.5.3	Calling Operation Routines . . . . .	2-13
2.5.3.1	Call with Macro Arguments . . . . .	2-13
2.5.3.2	Call with Arguments in Memory . . . . .	2-14
2.5.4	Handling Returns . . . . .	2-14
2.5.5	Examining Returned Values . . . . .	2-15
2.5.5.1	\$FETCH Macro . . . . .	2-15
2.5.5.2	\$COMPARE Macro . . . . .	2-16
2.5.5.3	\$TESTBITS Macro . . . . .	2-17
2.6	WRITING COMPLETION HANDLERS . . . . .	2-17
2.7	USING GET-SPACE ROUTINES . . . . .	2-18
2.7.1	Specifying Get-Space Routines . . . . .	2-18
2.7.2	Writing a Get-Space Routine . . . . .	2-19
2.7.2.1	Get-Space Routine Interface . . . . .	2-19
2.7.2.2	Pool Free-Space Lists . . . . .	2-19
2.8	ASSEMBLING THE PROGRAM . . . . .	2-20
2.8.1	Assembling with the RMSMAC Macro Library . . .	2-20
2.8.2	Assembly-Time Errors from RMS-11 Macros . . .	2-20

CONTENTS

CHAPTER 3 PROCESSING DIRECTORIES AND FILES

- 3.1 DEVICE CHARACTERISTICS . . . . . 3-1
- 3.2 LOGICAL CHANNELS . . . . . 3-2
- 3.3 FILE SPECIFICATIONS AND IDENTIFIERS . . . . . 3-2
- 3.4 PRIVATE BUFFER POOLS . . . . . 3-4
- 3.5 COMPLETION STATUS . . . . . 3-4
- 3.6 DIRECTORY OPERATIONS . . . . . 3-4
  - 3.6.1 RENAME Operation . . . . . 3-5
  - 3.6.2 PARSE Operation . . . . . 3-5
- 3.7 FILE OPERATIONS . . . . . 3-5
  - 3.7.1 CREATE Operation . . . . . 3-5
  - 3.7.2 OPEN Operation . . . . . 3-6
  - 3.7.3 DISPLAY Operation . . . . . 3-6
  - 3.7.4 ERASE Operation . . . . . 3-6
  - 3.7.5 EXTEND Operation . . . . . 3-6
  - 3.7.6 CLOSE Operation . . . . . 3-6
- 3.8 WRITING WILDCARD LOOPS . . . . . 3-7
  - 3.8.1 Introduction to Wildcarding . . . . . 3-7
    - 3.8.1.1 Initializing for Wildcarding . . . . . 3-7
    - 3.8.1.2 Finding the Next Matching File . . . . . 3-8
    - 3.8.1.3 Operating on the Found File . . . . . 3-8
    - 3.8.1.4 Ending Wildcarding . . . . . 3-8
  - 3.8.2 Nonselective ERASE or RENAME Wildcard Operations . . . . . 3-9
  - 3.8.3 Selective Wildcard Operations . . . . . 3-10

CHAPTER 4 PROCESSING RECORDS AND BLOCKS

- 4.1 COMPLETION STATUS . . . . . 4-1
- 4.2 STREAMS . . . . . 4-1
- 4.3 RECORD PROCESSING . . . . . 4-2
  - 4.3.1 Record Streams . . . . . 4-2
  - 4.3.2 Record Context . . . . . 4-2
  - 4.3.3 Record Access Modes . . . . . 4-3
    - 4.3.3.1 Sequential Access . . . . . 4-3
    - 4.3.3.2 Key Access . . . . . 4-4
    - 4.3.3.3 RFA Access . . . . . 4-5
  - 4.3.4 Record Buffers . . . . . 4-6
  - 4.3.5 Locate Mode . . . . . 4-6
  - 4.3.6 Stream Operations . . . . . 4-7
    - 4.3.6.1 CONNECT Operation . . . . . 4-7
    - 4.3.6.2 FLUSH Operation . . . . . 4-7
    - 4.3.6.3 FREE Operation . . . . . 4-7
    - 4.3.6.4 REWIND Operation . . . . . 4-8
    - 4.3.6.5 DISCONNECT Operation . . . . . 4-8
    - 4.3.7 Record Operations . . . . . 4-8
      - 4.3.7.1 FIND Operation . . . . . 4-8
      - 4.3.7.2 GET Operation . . . . . 4-8
      - 4.3.7.3 PUT Operation . . . . . 4-9
      - 4.3.7.4 DELETE Operation . . . . . 4-9
      - 4.3.7.5 UPDATE Operation . . . . . 4-9
      - 4.3.7.6 TRUNCATE Operation . . . . . 4-10
- 4.4 BLOCK PROCESSING . . . . . 4-10
  - 4.4.1 Block Streams . . . . . 4-10
  - 4.4.2 Block Context . . . . . 4-10
  - 4.4.3 Block Access Modes . . . . . 4-11
    - 4.4.3.1 Sequential Access . . . . . 4-11
    - 4.4.3.2 VBN Access . . . . . 4-11
  - 4.4.4 Block Buffers . . . . . 4-11
  - 4.4.5 Stream Operations . . . . . 4-12
    - 4.4.5.1 CONNECT Operation . . . . . 4-12
    - 4.4.5.2 FREE Operation . . . . . 4-12
    - 4.4.5.3 DISCONNECT Operation . . . . . 4-12
  - 4.4.6 Block Operations . . . . . 4-12
    - 4.4.6.1 READ Operation . . . . . 4-12

CONTENTS

4.4.6.2 WRITE Operation . . . . . 4-13

CHAPTER 5 OPERATION MACRO DESCRIPTIONS

5.1	\$CLOSE MACRO . . . . .	5-3
5.2	\$CONNECT MACRO . . . . .	5-5
5.3	\$CREATE MACRO . . . . .	5-8
5.4	\$DELETE MACRO . . . . .	5-24
5.5	\$DISCONNECT MACRO . . . . .	5-26
5.6	\$DISPLAY MACRO . . . . .	5-28
5.7	\$ERASE MACRO . . . . .	5-33
5.8	\$EXTEND MACRO . . . . .	5-38
5.9	\$FIND MACRO (SEQUENTIAL ACCESS) . . . . .	5-41
5.10	\$FIND MACRO (KEY ACCESS) . . . . .	5-43
5.11	\$FIND MACRO (RFA ACCESS) . . . . .	5-46
5.12	\$FLUSH MACRO . . . . .	5-48
5.13	\$FREE MACRO . . . . .	5-50
5.14	\$GET MACRO (SEQUENTIAL ACCESS) . . . . .	5-52
5.15	\$GET MACRO (KEY ACCESS) . . . . .	5-55
5.16	\$GET MACRO (RFA ACCESS) . . . . .	5-59
5.17	\$OPEN MACRO . . . . .	5-62
5.18	\$PARSE MACRO . . . . .	5-76
5.19	\$PUT MACRO (SEQUENTIAL ACCESS) . . . . .	5-81
5.20	\$PUT MACRO (KEY ACCESS) . . . . .	5-84
5.21	\$READ MACRO (SEQUENTIAL ACCESS) . . . . .	5-87
5.22	\$READ MACRO (VBN ACCESS) . . . . .	5-89
5.23	\$RENAME MACRO . . . . .	5-91
5.24	\$REWIND MACRO . . . . .	5-97
5.25	\$SEARCH MACRO . . . . .	5-99
5.26	\$TRUNCATE MACRO . . . . .	5-103
5.27	\$UPDATE MACRO . . . . .	5-105
5.28	\$WRITE MACRO (SEQUENTIAL ACCESS) . . . . .	5-107
5.29	\$WRITE MACRO (VBN ACCESS) . . . . .	5-109

CHAPTER 6 CONTROL BLOCK FIELDS

6.1	ALL BLOCK SUMMARY . . . . .	6-2
6.1.1	AID Field in ALL Block . . . . .	6-3
6.1.2	ALN Field in ALL Block (XB\$LBN Mask) . . . . .	6-4
6.1.3	ALQ Field in ALL Block . . . . .	6-5
6.1.4	AOP Field in ALL Block (XB\$CTG Mask) . . . . .	6-6
6.1.5	BKZ Field in ALL Block . . . . .	6-7
6.1.6	BLN Field in ALL Block (XB\$LAL Code) . . . . .	6-8
6.1.7	COD Field in ALL Block (XB\$ALL Code) . . . . .	6-9
6.1.8	DEQ Field in ALL Block . . . . .	6-10
6.1.9	LOC Field in ALL Block . . . . .	6-11
6.1.10	NXT Field in ALL Block . . . . .	6-12
6.2	DAT BLOCK SUMMARY . . . . .	6-13
6.2.1	BLN Field in DAT Block (XB\$DTL Code) . . . . .	6-14
6.2.2	CDT Field in DAT Block . . . . .	6-15
6.2.3	COD Field in DAT Block (XB\$DAT Code) . . . . .	6-16
6.2.4	NXT Field in DAT Block . . . . .	6-17
6.2.5	RDT Field in DAT Block . . . . .	6-18
6.3	FAB SUMMARY . . . . .	6-19
6.3.1	ALQ Field in FAB . . . . .	6-22
6.3.2	BID Field in FAB (FB\$BID Code) . . . . .	6-23
6.3.3	BKS Field in FAB . . . . .	6-24
6.3.4	BLN Field in FAB (FB\$BLN Code) . . . . .	6-25
6.3.5	BLS Field in FAB . . . . .	6-26
6.3.6	BPA Field in FAB . . . . .	6-27
6.3.7	BPS Field in FAB . . . . .	6-28
6.3.8	CTX Field in FAB . . . . .	6-29
6.3.9	DEQ Field in FAB . . . . .	6-30
6.3.10	DEV Field in FAB . . . . .	6-31

## PREFACE

### MANUAL OBJECTIVES

This manual is a guide to the use of RMS-11 in programs written in MACRO-11. It contains information necessary to writing MACRO-11 programs and subprograms that use RMS-11 operations.

### INTENDED AUDIENCE

This manual is intended for both the MACRO-11 programmer who wants to use RMS-11 operations and the high-level language programmer who wants to use RMS-11 operations in a MACRO-11 subprogram.

### STRUCTURE OF THIS DOCUMENT

- Chapter 1, Introduction to RMS-11 with MACRO-11, introduces RMS-11 macros and symbols that are the interface between a MACRO-11 program and RMS-11 operation routines.
- Chapter 2, RMS-11 Programming in MACRO-11, shows how to use RMS-11 macros and symbols in a MACRO-11 program.
- Chapter 3, Processing Directories and Files, shows how to use directory and file operations to process directories and files.
- Chapter 4, Processing Records and Blocks, shows how to use stream operations and either record or block operations to process records or blocks.
- Chapter 5, Operation Macro Descriptions, describes in detail each RMS-11 operation macro, the control blocks it uses, the options you can specify in each control block field, and the values returned in control block fields.
- Chapter 6, Control Block Fields, summarizes the use of each control block, field, value, and mask.
- Chapter 7, Example Programs, contains programs and program segments that illustrate the uses of some major RMS-11 features.

## PREFACE

- Appendix A, Completion Codes and Fatal Error Codes, lists RMS-11 completion symbols, values, and meanings.
- Appendix B, Assembly-Time Messages, lists the messages that RMS-11 macros can generate at assembly time.
- Appendix C, Macros That Declare Symbols and Other Macros, describes RMS-11 macros that declare other RMS-11 macros and define RMS-11 symbols.
- Appendix D, RMS-11 with Different Operating Systems, describes the differences among the behaviors of RMS-11 with various operating systems.
- The index includes a major entry for each RMS-11 macro, control block field mnemonic, keyword macro argument, and symbol family.

## ASSOCIATED DOCUMENTS

RSTS/E RMS-11: An Introduction introduces the major concepts of RMS-11, introduces the RMS-11 operations, and defines key terms required for understanding RMS-11 capabilities and functions. You should read the introduction before proceeding to other manuals in the RMS-11 documentation set.

The RSTS/E RMS-11 User's Guide provides detailed information for both MACRO-11 and high-level language programmers on file and task design using RMS-11.

The RSTS/E RMS-11 Utilities manual is both a user and a reference document for all users, both programmers and nonprogrammers. It describes the RMS-11 utilities that are available for creating and maintaining RMS-11 files.

In addition, the RSTS/E Quick Reference Guide is an easy-reference guide for users who are familiar with RMS-11 and its documentation. It summarizes the RMS-11 utilities and error codes.

## CONVENTIONS USED IN THIS DOCUMENT

The following conventions are used in statement formats in this document:

- |           |  |
|-----------|--|
| UPPERCASE | Uppercase characters within a string indicate characters that you must include in the string; you can type the characters in uppercase or lowercase. |
| lowercase | Lowercase characters within a string indicate a user-selected variable; text following the statement format defines the syntax of the variable.      |
| [ ]       | Square brackets indicate that the enclosed string is optional user input.  |
| ...       | A horizontal ellipsis indicates that the immediately preceding optional string (enclosed in square brackets) may be repeated.                        |

## PREFACE

From: DES.TMP In examples of commands you enter and system responses, all output lines and prompting characters that the system prints or displays are shown in black letters. All the lines you type are shown in red letters.

other A nonalphabetic character (except a square bracket or a period that is part of an ellipsis) indicates a character that you must include in the string.

Numbers in this manual that give the values of RMS-11 symbols are in octal radix (base 8) unless otherwise indicated; all other numbers in this manual are in decimal radix (base 10).

## SUMMARY OF TECHNICAL CHANGES

This revision contains the following technical changes:

- The new operation macros \$PARSE, \$RENAME, and \$SEARCH are documented, along with the related NAM block fields FNB, RSA, RSL, and RSS.
- The new facility for wildcard file specification is documented.
- The problems associated with non-write-shared access have been corrected.
- Random access to a sequential file with fixed-length records (similar to random access to a relative file) is documented.
- The new print-format record-output handling is documented, along with the related symbol FB\$PRN for the RAT field of the FAB.
- The new sequential block access is documented; the previous block access (formerly called block I/O) is now called VBN access (virtual block number access).
- Block access can now be used to copy RMS-11 files without the need to modify the file's attributes manually.
- The addition of the success handler facility for file operation macros (\$CLOSE, \$CREATE, \$DISPLAY, \$ERASE, \$EXTEND, and \$OPEN) is documented.
- Increased device transparency for record access copy operations is supported. VFC and stream record formats are supported on unit-record devices. Relative and indexed files can be created for record access on nondisk devices, although they will appear as and be processed as sequential files there.
- The obsolete RMS-11 initialization macros \$INIT and \$INITIF are no longer documented. These macros are now defined as no-ops in the RMS-11 macro library RMSMAC.MLB; their previous functions are no longer needed because RMS-11 is now self-initializing. However, programs that use the \$INIT and \$INITIF macros in their previous senses remain valid under RMS-11 Version 2.0.

## SUMMARY OF TECHNICAL CHANGES

- Each XAB type now has a distinct name; the following are the new names:

ALL block	Area allocation XAB
DAT block	File date XAB
KEY block	File key XAB
PRO block	File protection XAB
SUM block	File summary XAB

- The following symbol declaration macros are documented:

FAB\$BT	Declare FAB value and mask symbols
NAM\$BT	Declare NAM block value and mask symbols
RAB\$BT	Declare RAB value and mask symbols
XAB\$BT	Declare XAB value and mask symbols
XBAOF\$	Declare ALL block symbols
XBDOF\$	Declare DAT block symbols
XBKOF\$	Declare KEY block symbols
XBPOF\$	Declare PRO block symbols
XBSOF\$	Declare SUM block symbols

- The description of each operation macro includes the use and meaning of each associated control block field.
- The value of each RMS-11 user symbol is documented.
- The structure of each RMS-11 user control block is documented.
- The FAB has a new LRL (longest record length) field for sequential files (corresponding to the VAX-11 RMS XAB LRL field).
- The date/time XABs have changed in size from 36 to 46 octal bytes.
- For ANSI magtape, RMS-11 allows fixed-format records to be less than 18 bytes.
- <CTRL/Z> and <ESC> are no longer recognized as record terminators for stream files; and <CTRL/Z> is no longer recognized as a file terminator for stream files.
- RMS-11 now pads stream files with null characters to the high block of the file (not just to the end of the current block). This means that RMS-11-created stream files can be read by programs that do not recognize the EOF value from the file header.

## CHAPTER 1

### INTRODUCTION TO RMS-11 WITH MACRO-11

RMS-11 macros and symbols provide access to RMS-11 operations from a MACRO-11 program.

#### 1.1 ADVANTAGES OF USING RMS-11 MACROS

When you use RMS-11 operations from a high-level language, the language restricts your options for some operations. If you cannot accept these restrictions, you can write your program (or some of its modules) in MACRO-11; this allows you full access to RMS-11 options.

#### 1.2 RMS-11 MACROS AND SYMBOLS

RMS-11 macros and symbols define the interface between a MACRO-11 program and RMS-11 operation routines. Definitions for these macros and symbols are in the RMS-11 macro library, RMSMAC.MLB.

RMS-11 macros allow your program to:

- Call RMS-11 operations
- Declare and manipulate control blocks, through which your program communicates with RMS-11 operation routines
- Declare and manipulate space pools
- Declare needed RMS-11 facilities
- Extract (from the macro library RMSMAC.MLB) definitions for RMS-11 macros and symbols

The following sections introduce RMS-11 macros and symbols.

### 1.2.1 Operations

An RMS-11 operation macro calls a routine that performs an RMS-11 operation. The name of an operation macro is the name of the corresponding operation, with a prefixed dollar sign (\$). The following are the RMS-11 operation macros:

Directory Operation Macros	File Operation Macros	Stream Operation Macros	Record Operation Macros	Block Operation Macros
\$PARSE	\$CLOSE	\$CONNECT	\$DELETE	\$READ
\$RENAME	\$CREATE	\$DISCONNECT	\$FIND	\$WRITE
\$SEARCH	\$DISPLAY	\$FLUSH	\$GET	
	\$ERASE	\$FREE	\$PUT	
	\$EXTEND	\$REWIND	\$TRUNCATE	
	\$OPEN		\$UPDATE	

An RMS-11 operation returns a value called a completion code that indicates either a successful operation or an error. RMS-11 completion symbols give names to these completion codes.

When your program uses an RMS-11 operation macro to call an operation routine, it can specify completion handlers (one for a successful completion, one for an error completion) that RMS-11 calls when the operation completes. The RMS-11 completion-return macro (\$RETURN) generates a proper return from a completion handler to the calling point in your program.

### 1.2.2 Control Blocks and Fields

Your program and RMS-11 operation routines communicate by passing data in blocks called control blocks. Each control block is divided into fields; each field has a 3-letter mnemonic name.

An RMS-11 block-declaration macro allocates space for a control block and initializes fields containing the block length and block identifier. There is a block-declaration macro for each kind of control block.

An RMS-11 field-initialization macro sets an initial value for a control block field at assembly time. There are field-initialization macros for most control block fields (those that you might reasonably want to initialize).

An RMS-11 field-access macro manipulates the value of a control block field during program execution. There are field-access macros for copying values to and from fields (\$STORE and \$FETCH), for comparing field values with other values (\$COMPARE), and for setting, clearing, and testing bits in fields (\$SET, \$OFF, and \$TESTBITS).

RMS-11 code and mask symbols give names to the codes and bit masks used in many fields. This allows your program to determine the details of an RMS-11 operation without using the numeric values associated with those details.

RMS-11 field-offset symbols give names to the locations of fields within their control blocks. Because RMS-11 field-initialization and field-access macros are based on field names, your program need not use field-offset symbols.

RMS-11 control blocks and their general uses are as follows:

- ALL (area allocation) block - contains information about a file area.
- DAT (file date) block - contains file dates and the file revision number.
- FAB (file access block) - contains general information about a file and how a program will access it.
- KEY (file key) block - contains information about a file index and its key.
- NAM (file name) block - contains special information about the device, directory, and specification for the file, along with wildcarding information.
- PRO (file protection) block - contains file owner and protection information.
- RAB (record access block) - contains general information about a stream and a record or block, and how the program accesses the record or block.
- SUM (file summary) block - contains the number of areas and indexes in the file, and a version number indicating the internal structure level of the file.

### 1.2.3 Pools

RMS-11 conserves space by dynamically allocating and deallocating space set aside in pools. RMS-11 pool-declaration macros allocate space for pools.

An RMS-11 routine called the get-space routine handles pooled space. You can substitute your own get-space routine for the RMS-11 routine; you can use RMS-11 get-space-address macros to initialize the address of the get-space routine at assembly time (GSA\$), to change the address to that of a different routine during program execution (\$SETGSA), and to return the address of the current routine during program execution (\$GETGSA).

### 1.2.4 Facilities

The RMS-11 facilities-declaration macro (ORG\$) assists RMS-11 in determining exactly which routines your program needs during program execution.

### 1.2.5 Macros That Declare Symbols and Other Macros

To extract the definition of an RMS-11 macro from the macro library, your program must declare the macro in a .MCALL assembler directive.

Many RMS-11 macros declare related macros and define related symbols; some RMS-11 macros have the sole purpose of declaring related macros and defining related symbols. Using these macros simplifies the job of declaring macros and defining symbols in your program.

## INTRODUCTION TO RMS-11 WITH MACRO-11

For example, the FAB-declaration macro FAB\$B declares FAB field-initialization macros and FAB offset, code, and mask symbols; the \$FBCAL macro declares all directory and file operation macros; the \$RMSTAT macro declares all completion symbols.

## CHAPTER 2

### RMS-11 PROGRAMMING

To use RMS-11 operations in a MACRO-11 program, your program must:

- **Declare RMS-11 macros and symbols**

Before your program refers to an RMS-11 macro or symbol, it must extract its definition from the RMS-11 macro library. Section 2.1 shows how to declare macros and symbols.

- **Declare RMS-11 facilities**

To help RMS-11 decide which RMS-11 program modules are needed for your program, your program must declare some of the RMS-11 operations that it uses. Section 2.2 shows how to declare RMS-11 facilities.

- **Declare and use pool space**

RMS-11 dynamically allocates and deallocates space for some of its requirements; this space is separated into five pools. Using RMS-11 pool-declaration macros, you specify the size of each pool. Section 2.3 shows how to declare pool space.

- **Declare and initialize control blocks**

Your program and RMS-11 operation routines communicate by passing data back and forth in control block fields. Using RMS-11 block-declaration and field-initialization macros, your program allocates space for control blocks and (optionally) assigns initial values for fields. Section 2.4 shows how to declare and initialize control blocks.

- **Use RMS-11 operations**

Your program uses RMS-11 operation routines to perform record management services; the routines return values that show the results of the operations. Your program uses RMS-11 operation macros to call these operation routines. Section 2.5 shows how to call RMS-11 operation routines and how to handle returns from the routines.

Your program may also:

- **Include completion handlers**

An RMS-11 operation routine returns either a success completion code or an error completion code. Your program can include special routines (called success handlers and error handlers) that operation routines call automatically when operations complete. Section 2.6 shows how to write completion handlers.

- Use its own get-space routines

RMS-11 uses a routine (called a get-space routine) to allocate and deallocate space. RMS-11 has a get-space routine, but you can also supply others of your own. Section 2.7 shows how to use get-space routines and how to write a get-space routine.

Finally, you must:

- Assemble the program

When you assemble your program, it needs macro and symbol definitions from RMS-11; these are in a macro library, which your assembler command line must reference. RMS-11 macros detect some kinds of errors during assembly, and print messages that identify the errors. Section 2.8 shows how to assemble your program.

- Build the task

When you build your task, you must do one of the following:

- Use an RMS-11 resident library.
- Define an overlay structure for the task. RMS-11 offers several overlay definition (ODL) files from which you can select; you can also write your own ODL files.
- Include RMS-11 code in the task.

## 2.1 DECLARING RMS-11 MACROS AND SYMBOLS

Before your program refers to an RMS-11 macro or symbol, it must extract its definition from the RMS-11 macro library.

Your program can use the `.MCALL` assembler directive to extract the definition of any RMS-11 macro (but not a symbol) from the macro library. For example, to extract the definition of the macro `$CLOSE`, use the `.MCALL` directive in the format:

```
.MCALL $CLOSE ;Declare RMS-11 $CLOSE macro
```

Your program can use RMS-11 macros to extract definitions for RMS-11 symbols, and for some groups of other RMS-11 macros. Appendix C lists RMS-11 macros (with their arguments) that declare symbols and other macros.

## 2.2 DECLARING RMS-11 FACILITIES

To help RMS-11 decide which RMS-11 program modules your program needs, your program declares some of the operations that it uses. To do this, it uses the facilities-declaration macro `ORG$` in the format:

```
.MCALL ORG$ ;Declare ORG$ macro
ORG$ fileorg[,<operation[,operation]...]
```

where `fileorg` is a keyword indicating a file organization and each `operation` is a keyword indicating an operation that your program uses for a file of that organization.

A separate ORG\$ macro is required for each different file organization that your program processes, except that no ORG\$ macro is required for an organization that will be processed using only directory operations and block access.

The fileorg keyword argument to the ORG\$ macro is one of the following:

```

    IDX      Indexed file organization
    REL      Relative file organization
    SEQ      Sequential file organization

```

Each operation argument to an ORG\$ macro is one of the following:

```

    CRE      CREATE operation
    DEL      DELETE operation
    FIN      FIND operation
    GET      GET operation
    PUT      PUT operation
    UPD      UPDATE operation

```

These are the only operations that your program explicitly declares with the ORG\$ macro; support for other operations is handled automatically.

For example, suppose that your program:

- Creates both sequential and indexed files
- Uses FIND, GET, PUT, and UPDATE operations for sequential files
- Uses FIND, GET, PUT, and DELETE operations for indexed files

Then the proper ORG\$ macros are:

```

    ORG$    SEQ,<FIN,GET,PUT,UPD> ;Declare FIND, GET, PUT, and UPDATE
                                           ; operations for sequential files
    ORG$    IDX,<FIN,GET,PUT,DEL> ;Declare FIND, GET, PUT, and DELETE
                                           ; operations for indexed files

```

The results of ORG\$ macros are additive. For example, if one portion of your program specifies

```

    ORG$    SEQ,<GET,PUT>

```

and another specifies

```

    ORG$    SEQ,<GET,UPD>

```

then the effect is the same as specifying

```

    ORG$    SEQ,<GET,PUT,UPD>

```

Note also that all ORG\$ macros must occur in modules that are contained in the root segment of your task (not overlaid). Use of ORG\$ macros is optional in tasks linked with an RMS-11 memory-resident library.

## 2.3 DECLARING AND USING POOL SPACE

RMS-11 dynamically allocates and deallocates space for some of its requirements; this space is separated into five pools:

- Internal FAB and index descriptor block (IFAB/IDB) pool
- Internal RAB (IRAB) pool
- Key buffer pool
- I/O buffer pool
- Buffer descriptor block (BDB) pool

RMS-11 has a get-space routine that manages these pools, and that allocates and deallocates space to meet the needs of RMS-11 operations; however, you can supply other get-space routines and direct RMS-11 to use a different routine (and, optionally, different pools) instead of its own.

If you use only the RMS-11 get-space routine, declare pool space using the pool-declaration macros described below. If you use your own get-space routine, read Section 2.7; it shows how to write the routine, and how to manage the pools.

To declare space for pools, use pool-declaration macros in the format:

```

POOL$B                                ;Begin pool declarations
P$FAB  fabcount                        ;Space for IFABs in IFAB/IDB pool
P$IDX  indexcount                      ;Space for IDBs in IFAB/IDB pool
P$RAB  rabcount                        ;Space for IRABs for sequential
                                        ; and relative files and for
                                        ; block-accessed indexed files
                                        ; in IRAB pool
P$RABX  rabxcount,keysize,keychanges ;Space for IRABs for
                                        ; record-accessed indexed
                                        ; files in IRAB pool, and
                                        ; space for key buffers in
                                        ; key buffer pool
P$BUF  bufcount                        ;Space for I/O buffers in I/O
                                        ; buffer pool
P$BDB  bdbcount                        ;Space for BDBs in BDB pool
POOL$E                                ;End pool declarations

```

If your program uses multiple pool declarations, the results are cumulative.

The following sections show how to compute the values of arguments to the pool-declaration macros.

### 2.3.1 Internal FAB and Index Descriptor Block Pool

Internal FABs (IFABs) and index descriptor blocks (IDBs) are the same size and so share a pool (the IFAB/IDB pool). The total size of the pool is the sum of the following:

- The largest number of IFABs that your program uses at the same time, times 48 bytes. Specify this largest number of IFABs (not multiplied by 48) as the `fabcount` argument to the `P$FAB` macro.

A directory operation uses one IFAB, which is returned to the pool before the operation completes.

A `CREATE` or `OPEN` operation uses one IFAB, which is committed while the file is open; a `CLOSE` operation releases the IFAB. A `DISPLAY` or `EXTEND` operation uses no new IFABs; it uses the IFAB already committed to the open file. An `ERASE` operation uses one IFAB, which is released before the operation completes.

- The largest number of IDBs that your program uses at the same time, times 48 bytes. Specify this largest number of IDBs (not multiplied by 48) as the `indexcount` argument to the `P$IDX` macro.

Your program uses one IDB for each index of each indexed file opened for record access (rather than block access). The IDBs for an indexed file are committed when the file is opened (by a `CREATE` or `OPEN` operation) and are released when the file is closed (by a `CLOSE` operation).

### 2.3.2 Internal RAB Pool

Internal record access blocks (IRABs) have a separate pool. The size of the IRAB pool is the largest number of streams that your program will have connected at the same time, times the size of an IRAB (32 bytes).

Specify the largest number of streams connected to sequential files, relative files, and block-access indexed files (not multiplied by 32) as the `rabcount` argument to the `P$RAB` macro. Specify the largest number of streams connected to record-access indexed files as the `rabxcount` argument to the `P$RABX` macro.

If the sum of the `rabcount` and `rabxcount` arguments is larger than the largest number of streams that will ever be connected simultaneously, you may deduct the excess from the `rabcount` argument that you specify.

An IRAB is committed when a stream is connected and is released when the stream is disconnected or the file is closed (using the associated FAB).

### 2.3.3 Key Buffer Pool

Key buffers have a separate pool. (These key buffers are different from those specified by the KBF and KSZ fields of the RAB.)

Each time a stream is connected to an indexed file (for record access), the CONNECT operation requests space from the key buffer pool; the space is released when the stream is disconnected or the file is closed.

Compute the size (in bytes) of the request that the CONNECT operation makes as follows:

1. Begin with the size of the largest key for the file.
2. Multiply by 2.
3. Add the number of alternate keys for the file that are allowed to change during updating.
4. Add 1.
5. Round up (if necessary) to a multiple of 4.

If your program performs complex sequences of CONNECT and DISCONNECT (or CLOSE) operations for record-access indexed files with different key sizes, the key buffer pool may become fragmented (and therefore contain unusable space). In this case, the total size of the key buffer pool should be larger than the sum of the requirements for each connected stream.

Each P\$RABX macro that your program uses (in the format P\$RABX rabxcount, keysize, keychanges) allocates a number of bytes for the key buffer pool that is equal to

$$(\text{rabxcount}) \times ((\text{keysize} * 2) + \text{keychanges} + 1)$$

The expression  $((\text{keysize} * 2) + \text{keychanges} + 1)$  is rounded up (if necessary) to a multiple of 4.

You can use P\$RABX macros to precisely tailor the size of the key buffer pool, or to provide extra space against possible fragmentation problems. A good compromise is to choose the arguments to the P\$RABX macro as follows:

- Choose **rabxcount** as the largest number of streams that will be connected to record-access indexed files.
- Choose **keysize** as the largest key in any file that will be processed.
- Choose **keychanges** as the maximum number of changeable keys in any file that will be processed.

### 2.3.4 I/O Buffer Pool

The I/O buffers for RMS-11 operations come either from the central buffer pool or from a private buffer pool. (These are RMS-11 internal I/O buffers, and are different from the I/O buffers specified in the RBF, RSZ, UBF, and USZ fields of the RAB.)

Your program can specify a private buffer pool for a directory or file operation (except CLOSE, DISPLAY, or EXTEND). If your program does not specify a private buffer pool, these operations use the central buffer pool.

All other operations that require I/O buffers use the same pool as the CREATE or OPEN operation that opened the file.

The minimum size of the central I/O buffer pool is the sum of the sizes of the I/O buffers that your program will need from it at the same time (ignoring I/O buffers supplied from private buffer pools). Specify the size (in bytes) of the central buffer pool as the `iopoolsize` argument to the `P$BUF` macro.

Specify the size (in bytes) of a private buffer pool for an operation in the 1-word BPS field of the FAB and the address in the 1-word BPA field of the FAB. If your program specifies a private buffer pool for a CREATE or OPEN operation, the entire pool is reserved for and managed by that file until the file is closed.

Your program needs space from buffer pools for the following:

- One 512-byte I/O buffer for any directory or file operation (except CLOSE, DISPLAY, or EXTEND). This space is released before the operation completes.
- One 512-byte I/O buffer for a DISPLAY or EXTEND operation for a record-access relative or indexed file; the space is returned when the operation completes.
- I/O buffers for a CONNECT operation:
  - One I/O buffer for a record-access stream connected to a sequential disk file. The I/O buffer uses 512 bytes times the multiblock count for the stream.
  - One I/O buffer for a record-access stream connected to a sequential magtape file. The number of bytes in the I/O buffer is the block size for the file, rounded up (if necessary) to a multiple of 4 bytes.
  - One I/O buffer for a record-access stream connected to a file on a unit-record device. The number of bytes in the I/O buffer is equal to the default block size for the device, rounded up (if necessary) to a multiple of 4 bytes.
  - One or more I/O buffers for a stream connected to a relative file. Each I/O buffer uses 512 bytes times the bucket size for the file. If you use the multibuffer count to specify additional buffers, the requirement increases accordingly.
  - Two or more I/O buffers for a stream connected to an indexed file. Each I/O buffer uses 512 bytes times the bucket size for the file. If you use the multibuffer count to specify additional buffers, the requirement increases accordingly.

I/O buffers for a connected stream are retained until the stream is disconnected by a DISCONNECT or CLOSE operation.

If your program uses the I/O buffer pool for complex sequences of operations that use I/O buffers for different files, the pool may become fragmented. In that case, you may want to either allocate extra space in the I/O buffer pool, or limit fragmentation through the judicious use of private buffer pools.

### 2.3.5 Buffer Descriptor Block Pool

Your program requires one 20-byte buffer descriptor block (BDB) for each I/O buffer (whether from the central or a private pool) that it uses at the same time; these BDBs are allocated and returned at the same time as their associated I/O buffers. (I/O buffer requirements are described in the previous section.)

In addition, a block-access stream (for any file) or a record-access stream that will write to a relative file requires an additional BDB; a record-access stream that will write to an indexed file requires two additional BDBs. These BDBs are returned when the stream is disconnected (or the file is closed).

An EXTEND operation for a record-access relative or indexed file also requires an additional BDB, which is returned when the operation completes.

Therefore the size of the BDB pool is the largest number of BDBs required at any one time, times 20 bytes. Specify this largest number of BDBs (not multiplied by 20) as the `bdbcount` argument to the `P$BDB` macro.

## 2.4 DECLARING AND INITIALIZING CONTROL BLOCKS

Your program and RMS-11 operation routines communicate by passing data back and forth in control block fields. Using RMS-11 block-declaration and field-initialization macros, you allocate space for control blocks and (optionally) assign initial values for fields.

To declare a control block and initialize its fields, use block-declaration and field-initialization macros as follows:

1. Make sure the control block is word-aligned by using the `.EVEN` directive:

```
.EVEN                ;Word-align block
```

2. Specify a label so that your program can refer symbolically to the address of the control block.

```
label:
```

3. Begin the block declaration with one of the following macros:

```
FAB$B                ;Begin FAB declaration
NAM$B                ;Begin NAM block declaration
RAB$B                ;Begin RAB declaration
XAB$B   XB$ALL       ;Begin ALL block declaration
XAB$B   XB$DAT       ;Begin DAT block declaration
XAB$B   XB$KEY       ;Begin KEY block declaration
XAB$B   XB$PRO       ;Begin PRO block declaration
XAB$B   XB$SUM       ;Begin SUM block declaration
```

4. Initialize (optionally) fields with field-initialization macros of one of the forms:

```

F$fld  arg           ;Initialize FAB field
N$fld  arg           ;Initialize NAM block field
R$fld  arg           ;Initialize RAB field
X$fld  arg           ;Initialize XAB field

```

In each of these forms, fld is the mnemonic for a field in the control block; arg is an argument suitable for the value of the field. Chapter 6 describes field-initialization macros and their arguments.

5. End the block declaration with one of the following macros:

```

FAB$E           ;End FAB declaration
NAM$E           ;End NAM block declaration
RAB$E           ;End RAB declaration
XAB$E           ;End XAB declaration

```

## 2.5 USING RMS-11 OPERATIONS

Your program uses RMS-11 operation routines to perform record management services. Using RMS-11 operation macros, you call these operation routines. The routines return values in control block fields that show the results of the operations.

To use RMS-11 operation routines, your program must:

- **Set up control block fields**

The values that your program places in control block fields specify the details of the service you want from the RMS-11 operation routine. Section 2.5.1 shows how to set up control block fields.

- **Chain control blocks**

Some RMS-11 operation routines (stream, record, and block operation routines) read only RAB fields; others (directory and file operation routines) read FAB fields and, if your program supplies them, fields in NAM blocks and XABs. Your program chains these blocks (using address pointers) so that the operation routine can find them. Section 2.5.2 shows how to chain control blocks.

- **Call operation routines**

You use RMS-11 operation macros to call RMS-11 operation routines. Section 2.5.3 shows how to call operation routines.

- **Handle returns**

Section 2.5.4 shows how to handle returns from operation routines.

- **Examine returned values**

When an RMS-11 operation routine completes its execution, it has placed values in control block fields that show the results of the operation. Your program should examine these values to determine the results. Section 2.5.5 shows how to examine returned values.

### 2.5.1 Setting Up Control Block Fields

The values that your program places into control block fields specify the details of the service you want from the RMS-11 operation routine. The description of each operation macro in Chapter 5 discusses the control block fields that are read by that operation.

Three RMS-11 field-access macros help you place values into control block fields:

- \$STORE places a specified value into a field.
- \$SET sets bits in a field.
- \$OFF clears bits in a field.

**2.5.1.1 \$STORE Macro** - Use the \$STORE macro to copy a value from a specified location to a control block field. The format for the \$STORE macro is:

```
$STORE src,fld,reg
```

where **src** is a an address in memory; **fld** is a field mnemonic; and **reg** is a general purpose register (R0 through R5) containing the address of the control block.

The \$STORE macro looks up the size of the destination field, so that it can copy the correct number of bytes or words. If the source is a register and the destination is a 1-byte field, then the low byte of the register is copied; if the source is a register and the destination is a multiword field, then the contents of the specified register and following registers are copied.

The \$STORE macro generates an error during assembly if you use an illegal address mode for the source. For multiword fields, illegal address modes are autoincrement deferred, autodecrement deferred, and indexed deferred.

It is also illegal to specify the program counter (PC) as the source or to specify a register as source in such a way that the source overlaps the register that contains the control block address.

At execution time, the \$STORE macro copies the contents of the specified location to the control block field. The number of bytes or words copied is the same as the field size for the mnemonic. Chapter 6 gives the size of each control block field.

For example, suppose that you want to specify indexed file organization in the FAB for a file, and suppose that the address of that FAB is stored in register R2. Then the proper macro is:

```
$STORE #FB$IDX,ORG,R2 ;Indexed file organization
```

Suppose that you want to chain a NAM block whose label is NAMBLK to the same FAB. Then the proper macro is:

```
$STORE #NAMBLK,NAM,R2 ;Chain NAM block
```

Suppose that you want to set the allocation quantity (ALQ field) of the same FAB to the value stored in a location labeled ALQVAL. Then the proper macro is:

```
$STORE ALQVAL,ALQ,R2 ;Load allocation quantity
```

and (because ALQ is a 2-word field) two words are copied from ALQVAL to the ALQ field.

**2.5.1.2 \$SET Macro** - Use the \$SET macro to set bits in a 1-byte or 1-word control block field. The \$SET macro logically ORs a given mask into the control block field. Therefore for each bit set in the mask, the \$SET macro sets the corresponding bit in the field; the other bits are not changed.

Note that you use the \$SET macro only if you want to leave some bits in a field undisturbed; if you want to set specified bits and clear all others, use the \$STORE macro.

The format for the \$SET macro is:

```
$SET mask,fld,reg
```

where **mask** is an address in memory containing bits to be set; **fld** is the mnemonic for a control block field; and **reg** is a general purpose register (R0 through R5) containing the address of the control block.

If the field is not a 1-byte or 1-word field, the \$SET macro generates an error during assembly.

RMS-11 has symbols for masks for each bit-oriented control block field. Therefore your program can use these symbols instead of numerical values.

For example, suppose you want to specify rewind-on-close in the FAB for a file, but do not want to disturb other bits in the FOP field of the FAB; suppose also that the address of the FAB is in register R2. Then the proper macro is:

```
$SET #FB$RWC,FOP,R2 ;Rewind-on-close
```

As another example, suppose you want to specify key-duplicates-allowed and key-changes-allowed for an index, but do not want to disturb other bits in the FLG field of the KEY block; suppose also that the address of the KEY block is in register R4. Then the proper macro is:

```
$SET #XB$DUP!XB$CHG,FLG,R4 ;Allow key duplicates and changes
```

**2.5.1.3 \$OFF Macro** - Use the \$OFF macro to clear bits in a 1-byte or 1-word control block field. The \$OFF macro logically ANDs the 1's complement of a given mask into the control block field. Therefore for each bit set in the mask, it clears the corresponding bit in the field; the other bits are not changed.

Note that you use the \$OFF macro only if you want to leave some bits in a field undisturbed; if you want to clear the entire field, use the \$STORE macro (with a source value of #0).

## RMS-11 PROGRAMMING

The format for the \$OFF macro is:

```
$OFF mask, fld, reg
```

where **mask** is an address in memory containing bits to be cleared; **fld** is the mnemonic for a control block field; and **reg** is a general purpose register (R0 through R5) containing the address of the control block.

If the field is not a 1-byte or 1-word field, the \$OFF macro generates an error during assembly.

RMS-11 has symbols for masks for each bit-oriented control block field. Therefore your program can use these symbols instead of numerical values.

For example, suppose you want to specify no-rewind-on-close in the FAB for a file, but do not want to disturb other bits in the FOP field of the FAB; suppose also that the address of the FAB is in register R2. Then the proper macro is:

```
$OFF #FB$RWC, FOP, R2           ;No rewind-on-close
```

As another example, suppose you want to specify no-key-duplicates-allowed and no-key-changes-allowed for an index, but do not want to disturb other bits in the FLG field of the KEY block; suppose also that the address of the KEY block is in register R4. Then the proper macro is:

```
$OFF #XB$DUP!XB$CHG, FLG, R4    ;No key duplicates or changes
```

### 2.5.2 Chaining Control Blocks

An RMS-11 directory operation or file operation uses at least one FAB; you specify FABs in the operation macros that call the operation routines.

For some directory operations, a NAM block is required; it is optional for other directory operations and for file operations. You specify a NAM block and XABs for an operation by chaining them to the FAB for the operation.

**2.5.2.1 Chaining a NAM Block to a FAB** - Specify the NAM block associated with a FAB by placing its address in the 1-word NAM field of the FAB.

**2.5.2.2 Chaining XABs to a FAB** - Specify the XABs associated with a FAB by placing the address of the first XAB in the 1-word XAB field of the FAB; in each XAB, specify the address of the next XAB in the chain in the 1-word NXT field of the XAB; in the last XAB in the chain, specify 0 in the NXT field.

Follow these rules in ordering XABs in a chain:

- Place ALL blocks together in the chain. Each ALL block is "numbered" by the value in the 1-byte AID field of the ALL block; chain ALL blocks so that these numbers are in ascending order. For the CREATE operation, begin with 0 and do not skip numbers in the ascending sequence; for other operations, you can skip numbers in the sequence.

- Place no more than one DAT block in the chain.
- Place KEY blocks together in the chain. Each KEY block is "numbered" by the value in the 1-byte REF field of the KEY block; chain KEY blocks so that these numbers are in ascending order. For the CREATE operation, begin with 0 and do not skip numbers in the ascending sequence; for other operations, you can skip numbers in the sequence.
- Place no more than one PRO block in the chain.
- Place no more than one SUM block in the chain.

**2.5.2.3 Chaining a FAB to a RAB (CONNECT Operation)** - The CONNECT operation creates a stream for a file. A FAB specifies the file; a RAB specifies the stream. Specify the address of the FAB for the file in the 1-word FAB field of the RAB for the stream.

### 2.5.3 Calling Operation Routines

Use RMS-11 operation macros to call operation routines. You can specify arguments for the operation routine either by giving them as arguments to the operation macro, or by placing them in an argument block in memory.

**2.5.3.1 Call with Macro Arguments** - Call an operation routine (except RENAME) using an operation macro with arguments in the format:

```
$macroname blkaddr[, [erraddr][, sucaddr]]
```

where **\$macroname** is the name of an operation macro (except \$RENAME); **blkaddr** is the address of a FAB (for a directory or file operation) or a RAB (for a stream, record, or block operation); **erraddr** is the address of an error handler for the operation; and **sucaddr** is the address of a success handler for the operation.

For example, if you want to open a file using a FAB at address INFAB and want to use a success handler at address SUCCES, the macro call would be:

```
$OPEN #INFAB,,#SUCCES
```

Call the RENAME operation using the \$RENAME operation macro with arguments in the format:

```
$RENAME oldfabaddr, [erraddr], [sucaddr], newfabaddr
```

where **oldfabaddr** is the address of a FAB for the old file specification; **erraddr** is the address of an error handler for the operation; **sucaddr** is the address of a success handler for the operation; and **newfabaddr** is the address of a FAB for the new file specification.

**2.5.3.2 Call with Arguments in Memory** - To call an operation routine using an operation macro with arguments in an argument block in memory, omit the arguments to the macro, store the address of the argument block in register R5, and store the argument block in memory as follows:

1	0	ARGUMENT COUNT	0
	ADDRESS OF FAB OR RAB		2
	ADDRESS OF ERROR HANDLER (OPTIONAL)		4
	ADDRESS OF SUCCESS HANDLER (OPTIONAL)		6
	ADDRESS OF NEW FAB (RENAME ONLY)		10

ZK-1097-82

The argument count is 4 for a RENAME operation; otherwise it is one of the following:

- 1 - no completion handlers
- 2 - error handler, but no success handler
- 3 - success handler

If the operation has no error handler, but either has a success handler or the operation is RENAME, specify -1 as the address of the error handler; if the operation has no success handler, but the operation is RENAME, specify -1 as the address of the success handler.

#### 2.5.4 Handling Returns

An RMS-11 file or directory operation returns a completion status code in the 1-word STS field of the FAB and, for some completions, a completion status value in the 1-word STV field of the FAB.

An RMS-11 stream, record, or block operation returns a completion status code in the 1-word STS field of the RAB and, for some completions, a completion status value in the 1-word STV field of the RAB.

Appendix A lists completion codes.

Your program should examine the STS field contents to determine whether the operation was successful; even if the operation returned an error completion, your program may be able to handle the error and recover.

The program can handle the return (based on the completion code) either in the code that immediately follows the operation macro, or in special routines (called completion handlers) that the operation can call. Section 2.6 shows how to write completion handlers.

There are two kinds of fatal RMS-11 errors:

- If the FAB or RAB address you specify is not the address of a valid and idle FAB or RAB, or if the argument block you provide is invalid, RMS-11 cannot return values, even in the STS field. RMS-11 issues a BPT instruction, leaving status information in the following registers:

R0: RMS-11 fatal error code  
 R1: Stack pointer (at time of entry to RMS-11 routine)  
 R2: Program counter (entry return same as @R1)  
 R3: Address of system impure area

- If RMS-11 detects the corruption of memory-resident data structures, or if it detects inconsistent internal states, it cannot proceed with its operations. In these cases, RMS-11 halts execution with a BPT instruction; if it can identify the error, RMS-11 leaves an error completion in R0.

Appendix A lists the symbols and values for RMS-11 fatal error codes.

### 2.5.5 Examining Returned Values

When an RMS-11 operation routine completes its execution, it has placed values in control block fields that show the results of the operation. Your program should examine these values to determine the results. The description of each operation macro in Chapter 6 discusses the control block fields that return values for that operation.

Three RMS-11 field-access macros help you examine values in control block fields:

- \$FETCH copies a value from a field to a specified location.
- \$COMPARE compares a field value to a specified value.
- \$TESTBITS determines whether specified bits in a field are set.

**2.5.5.1 \$FETCH Macro** - Use the \$FETCH macro to copy a value from a control block field to a specified location. The format for the \$FETCH macro is:

```
$FETCH dst, fld, reg
```

where **dst** is an address in memory; **fld** is the mnemonic for a control block field; and **reg** is a general purpose register (R0 through R5) containing the address of the control block.

The \$FETCH macro looks up the size of the source field, so that it can copy the correct number of bytes or words. If the destination is a register and the source is a 1-byte field, then the byte is copied to the low byte of the register and the high byte is cleared. If the destination is a register and the source is a multiword field, then the multiword field is copied to the specified register and following registers.

The \$FETCH macro generates an error during assembly if you use an illegal address mode for the destination. For multiword fields, illegal address modes are autoincrement deferred, autodecrement deferred, and indexed deferred. Immediate mode is illegal for \$FETCH, regardless of field size.

It is also illegal to use the program counter (PC) as the destination or to specify a register for the destination in such a way that the destination overlaps the register that contains the control block address.

At execution time, the \$FETCH macro copies the contents of the control block field to the specified location. The number of bytes or words copied is the same as the field size for the mnemonic. Chapter 6 gives the size of each control block field.

As an example of the use of the \$FETCH macro, suppose that you want to fetch the allocation quantity (ALQ field) from a FAB to a location labeled ALQSAV, and suppose also that the address of the FAB is in register R3. Then the proper macro is:

```
$FETCH ALQSAV,ALQ,R3          ;Save allocation quantity
```

and two words are copied from the ALQ field to memory beginning at ALQSAV.

**2.5.5.2 \$COMPARE Macro** - Use the \$COMPARE macro to compare the contents of a 1-byte or 1-word control block field with a specified value. The format for the \$COMPARE macro is:

```
$COMPARE src,fld,reg
```

where **src** is an address in memory; **fld** is the mnemonic for a control block field; and **reg** is a general purpose register (R0 through R5) containing the address of the control block.

If the given field is not a 1-byte or 1-word field, the \$COMPARE macro generates an error during assembly.

At execution time, the \$COMPARE macro executes a machine instruction that compares the source value and the field contents. The instruction executed depends on the size of the specified field and on the specified source:

- TSTB for a 1-byte field and the source #0
- TST for a 1-word field and the source #0
- CMPB for a 1-byte field and a source other than #0
- CMP for a 1-word field and a source other than #0

Chapter 6 gives the size of each control block field.

For example, suppose that you want to compare the value in the RSZ field of a RAB with a value stored in a location labeled RSZSAV, and suppose also that the address of the RAB is stored in register R2. Then the proper macro is:

```
$COMPARE RSZSAV,RSZ,R2          ;Compare record size
```

Suppose that you want to compare the same RSZ field to the value of a symbol, RECSIZ. Then the proper macro is:

```
$COMPARE #RECSIZ,RSZ,R2      ;Compare record size
```

**2.5.5.3 \$TESTBITS Macro** - Use the \$TESTBITS macro to test the values of bits in a 1-byte or 1-word control block field. Chapter 6 gives the size of each control block field. The format for the \$TESTBITS macro is:

```
$TESTBITS mask,fld,reg
```

where **mask** is an address in memory containing bits to be tested; **fld** is the mnemonic for a control block field; and **reg** is a general purpose register (R0 through R5) containing the address of the control block.

If the given field is not a 1-byte or 1-word field, the \$TESTBITS macro generates an error during assembly.

At execution time, the \$TESTBITS macro executes a machine instruction that tests the bits specified in the mask. The instruction executed depends on the size of the specified field:

- BITB for a 1-byte field
- BIT for a 1-word field

For example, suppose you want to determine whether the terminal device is set in the DEV field of a FAB, and suppose that the address of the FAB is in register R3. Then the proper macro is:

```
$TESTBITS #FB$TRM,DEV,R3      ;Terminal device?
```

As another example, suppose that you want to determine whether either the contiguous-area or the hard-location bit is set in the AOP field of an ALL block, and suppose that the address of the ALL block is in register R2. Then the proper macro is:

```
$TESTBITS #XB$CTG!XB$HRD,AOP,R2 ;Contiguous or hard location?
```

## 2.6 WRITING COMPLETION HANDLERS

Recall that when you use an RMS-11 operation macro, you can specify the addresses of completion handlers for the operation; if you do so, the operation automatically calls the error handler (for a nonfatal error completion) or the success handler (for a success completion) when the operation completes, before control returns to your program.

When execution control passes to your completion handler, it finds the following situation:

- Register R5 contains the address of the argument block for the operation.
- The second word of the argument block contains the address of the FAB or RAB for the operation. (Recall that the STS and STV fields of the FAB or RAB contain the completion code and completion value for the operation.)

## RMS-11 PROGRAMMING

- If the operation was RENAME, the fifth word of the argument block contains the address of a second FAB for the operation.
- Other blocks are chained as they were when you used the operation macro that called the operation routine.

A completion handler cannot determine from these values which RMS-11 operation was executed, or what part of your program called the operation routine. You can, however, use the 1-word CTX field of the FAB or the 1-word CTX field of the RAB to indicate the context of the operation; RMS-11 does not disturb values in CTX fields.

The completion handler must preserve the stack pointer (SP), and must end with the RMS-11 completion-return macro in the format:

```
$RETURN                                ;End of completion handler
```

### 2.7 USING GET-SPACE ROUTINES

Your program can provide and use get-space routines other than the one provided with RMS-11. It can set an initial get-space routine at assembly time, and it can change to other routines during program execution. Section 2.7.1 shows how to specify get-space routines, and how to obtain the address of the current get-space routine. Section 2.7.2 shows how to write a get-space routine.

#### 2.7.1 Specifying Get-Space Routines

To specify a get-space routine at assembly time, use the GSA\$ macro in the format:

```
GSA$    address                        ;Initialize get-space routine
                                           ; address
```

where **address** is the **get-space routine entry address**. If you specify 0 as the address, or if you do not use the GSA\$ macro, the initial get-space routine for the program is the RMS-11 routine.

For example, to specify a routine that begins at the label MYSPAC, you would use:

```
GSA$    MYSPAC
```

To change the get-space routine during program execution, use the \$SETGSA macro in the format:

```
$SETGSA pointer                        ;Change get-space routine
```

where **pointer** is the **address of a location that contains the get-space routine entry address**. If you specify the entry-point address as 0, the new get-space routine established is the RMS-11 routine.

For example, to specify a routine that begins at the label NEWSPC, you could use:

```
$SETGSA #NEWSPC
```

Alternatively, if the location GSATMP contains the value NEWSPC, you could use:

```
$SETGSA GSATMP
```

To obtain the address (in R0) of the current get-space routine during program execution, use the \$GETGSA macro in the format:

```
$GETGSA                                ;Get-space routine address into R0
```

If the address returned in R0 is 0, the current get-space routine is the RMS-11 routine.

## 2.7.2 Writing a Get-Space Routine

A get-space routine handles space in contiguous blocks. For a request for space, it allocates a contiguous block of space (or denies the request); for a release of space, it accepts a contiguous block of space.

A get-space routine must have a proper interface to calling routines, and it should handle unallocated space properly.

**2.7.2.1 Get-Space Routine Interface** - When RMS-11 calls a get-space routine, it either requests or releases a block of space. For a request for space, registers R0 through R2 contain the following values:

```
R0  Address of pool free-space list (see next section)
R1  Size (in bytes) of requested block
R2  0
```

If the get-space routine fills the request, it must clear the C bit and return the address of the first word of the allocated block in R0; if it does not fill the request, it must set the C bit. In either case, the routine must preserve the stack and registers R3 through R6.

For a release of a block of space, registers R0 through R2 contain the following values:

```
R0  Address of pool free-space list (see next section)
R1  Size (in bytes) of released block
R2  Address of first word being released
```

For a release-space operation, the get-space routine returns no values; however, it must preserve the stack and registers R3 through R6.

**2.7.2.2 Pool Free-Space Lists** - When RMS-11 calls your get-space routine, the address of a pool free-space list is in register R0. This free-space list specifies free space in one of the five pools described in Section 2.3; you can use this pool (which may or may not have adequate free space), or you can use a pool of your own.

The free-space list chains free contiguous blocks of the pool. The first word of each block contains the address of the next block; if the first word of a block is 0, it is the last block in the list.

Blocks in the list are ordered by ascending virtual addresses; their addresses are word-aligned; their sizes are multiples of 4 bytes (allocations and deallocations must be rounded up to a multiple of 4, if necessary).

## RMS-11 PROGRAMMING

The second word of each block contains the size (in bytes) of the block, including the 4-byte header; the first "block" in the list contains 0 in its second word, since it is the header block for the list.

Your get-space routine can use the specified pool list to get space for RMS-11; if it does this, it must properly maintain the list, and must (if possible) merge blocks back into the pool.

The system routines \$RQCB and \$RLCB are suitable for handling pool free-space lists. These routines have interfaces that meet the requirements for your get-space routine; therefore your program can jump to \$RQCB (for a space request) or \$RLCB (for a space release).

### 2.8 ASSEMBLING THE PROGRAM

When you assemble your program, you must cause the assembler to get RMS-11 macro and symbol definitions from a library, and you may have to correct errors indicated by messages from RMS-11 macros.

#### 2.8.1 Assembling with the RMSMAC Macro Library

When you assemble your program, the assembler needs definitions for the RMS-11 macros and symbols that your program uses; these are in the RMS-11 macro library, RMSMAC.MLB. Include the following reference to the RMS-11 macro library in your assembler command string:

```
LB:RMSMAC.MLB/ML
```

#### 2.8.2 Assembly-Time Errors from RMS-11 Macros

RMS-11 macros detect some errors during assembly. For each such error, a macro issues a .PRINT or .ERROR assembler directive with a message. Appendix B describes RMS-11 macro-generated messages and their meanings.

## CHAPTER 3

### PROCESSING DIRECTORIES AND FILES

This chapter discusses use of RMS-11 directory and file operations. The next sections discuss information and usage common to several directory and file operations:

- Device characteristics
- Logical channels
- File specifications and identifiers
- Private buffer pools
- Completion status

The sections after those provide an overview of the operations themselves (see Chapter 5 for detailed discussions):

- Directory operations (except SEARCH): RENAME and PARSE
- File operations: CREATE, OPEN, DISPLAY, ERASE, EXTEND, and CLOSE

Finally, the last sections discuss:

- SEARCH operation
- Writing wildcard loops

#### 3.1 DEVICE CHARACTERISTICS

A directory or file operation (except CLOSE, DISPLAY, or EXTEND) returns device characteristics. These characteristics are returned as masks in the 1-byte DEV field of the FAB. The device characteristics are:

- Printer or terminal (indicated by the set FB\$CCL mask in the 1-byte DEV field of the FAB and the set FB\$REC mask in the 1-byte DEV field of the FAB; for a terminal, the FB\$TRM mask in the 1-byte DEV field of the FAB is also set); RMS-11 treats a printer or terminal as a unit-record device.
- Disk, DEctape, or DECTAPE II (indicated by the set FB\$MDI mask in the 1-byte DEV field of the FAB); RMS-11 treats a disk, DEctape, or DECTAPE II as a disk device.
- Unit-record device (indicated by the set FB\$REC mask in the 1-byte DEV field of the FAB).

## PROCESSING DIRECTORIES AND FILES

- Non-ANSI magtape or cassette tape (indicated by the set FB\$SDI mask in the 1-byte DEV field of the FAB and the set FB\$REC mask in the 1-byte DEV field of the FAB); RMS-11 treats a non-ANSI magtape or a cassette tape as a unit-record device.
- ANSI-format magtape (indicated by the set FB\$SQD mask in the 1-byte DEV field of the FAB).

### 3.2 LOGICAL CHANNELS

An RMS-11 directory or file operation (except CLOSE, DISPLAY, or EXTEND) requires a logical channel; this channel is a path from the program to a specified device.

When your program executes a CREATE or OPEN operation on the channel, the path is extended to the target file; until the file is closed, the channel is reserved for the specified FAB.

Your program specifies the logical channel for a directory operation or for a CREATE, ERASE, or OPEN operation in the 1-byte LCH field of the FAB; the channel must not already be in use by the task.

You can specify the initial device assignment for a logical channel in a Task Builder command file. The Task Builder also provides default initial device assignments for certain channels. Other logical channels are unassigned when your task begins executing.

During task execution, channel assignments are made or changed by use of the ALUN\$ system directive. For example, RMS-11 uses the ALUN\$ directive to assign a logical channel for a directory operation or for a CREATE, ERASE, or OPEN operation; if the FAB and NAM block specify a device or device identifier, RMS-11 assigns the channel to that device; if the FAB and NAM block do not specify a device or device identifier, RMS-11 retains the device-channel assignment (if any), or assigns the channel to the device SY:.

### 3.3 FILE SPECIFICATIONS AND IDENTIFIERS

A file specification consists of the following elements (in the order given):

- Device specification - the device where the file resides
- Directory specification - the directory on the device through which the file can be found
- File name - the name by which the file is known in the directory
- File type - the type by which the file is known in the directory

RMS-11 operations construct and use file specification strings and file identifiers to specify files. These strings and identifiers include:

- User-provided file specification strings
- Expanded file specification strings

- Resultant file specification strings
- File and device identifiers

This section discusses these strings and identifiers as they are used for nonwildcard operations; wildcard use is described in Section 3.8.

For a CREATE, ERASE, OPEN, PARSE, or RENAME operation, your program specifies two strings to be used in generating a full file specification:

- A file specification string, called the **file string** (your program specifies the address of the file string in the 1-word FNA field of the FAB and the length of the string in the 1-byte FNS field of the FAB)
- A default file specification string, called the **default string** (your program specifies the address of the default string in the 1-word DNA field of the FAB and the length of the string in the 1-byte DNS field of the FAB)

The operation routine uses these two strings to form an internal merged file specification string, called the **merged string**. The operation initially forms the merged string as follows:

- It begins by taking available elements from the file string.
- It then supplies missing elements from the default string (if they are available there). The operation (when it completes) returns masks describing the results of this merge in the 1-word FNB field of the NAM block (if you supplied a NAM block for the operation).

If elements are still missing from the merged string, the operation next adds the following elements:

- Device - If the logical channel specified in the LCH field of the FAB is already assigned to a device, that device is used; otherwise the device SY: is used.
- Directory - The task's current directory is used.
- File name and type - Nulls are used.

If the operation is the PARSE operation, the merged string is complete. If you provided a NAM block, the PARSE operation returns the device identifier in the 2-word DVI field of the NAM block; if you provided an expanded string buffer, the PARSE operation returns the expanded string in the expanded string buffer (whose address is in the 1-word ESA field of the NAM block). (Note that the device specification in an expanded string has usually been translated to the specification for a physical device.)

An operation other than PARSE continues by examining the FB\$FID mask in the FOP field of the FAB. If the FB\$FID mask is set, the operation adds the following elements:

- Device - If a device identifier is given in the NAM block, that device overrides the device in the merged string and the device specification is deleted from the merged string.
- File identifier - If a file identifier is given in the NAM block and if the operation is ERASE or OPEN, that file overrides the file name and type in the merged string and the specifications for those elements are deleted from the merged string.

## PROCESSING DIRECTORIES AND FILES

The merged string is then copied to the expanded string buffer (if you supplied one) as described for the PARSE operation above. The merged string plus applicable identifiers are called the **fully qualified file specification**, and define the file upon which the operation will be performed.

The device and file identifiers for the file are returned in the NAM block (if you supplied one). If the operation is SEARCH, the file identifier will be returned only if the FB\$FID mask is set.

Note that a complete file specification is relevant only to a disk file. The directory specification is not relevant for ANSI magtape files; only the device specification is relevant for a file on a unit-record device. Irrelevant elements are not processed, and appear in the expanded string only if your program provides them in the file string or default string.

### 3.4 PRIVATE BUFFER POOLS

Many RMS-11 operations require space from a buffer pool. A directory or file operation (except CLOSE, DISPLAY, or EXTEND) allows your program to specify a private buffer pool. Your program specifies the address of the pool in the 1-word BPA field of the FAB; it specifies the size (in bytes) of the pool in the 1-word BPS field of the FAB.

The CLOSE operation returns (in the BPA and BPS fields) the address and size of the private buffer pool (if any) specified for the CREATE or OPEN operation that opened the file; until the file is closed, the pool is dedicated to the open file and must not be used for other purposes.

If your program does not specify a private buffer pool, the operation uses the central buffer pool (which your program declares using pool-declaration macros); if your program specifies a private buffer pool, the operation uses that pool.

The CLOSE, DISPLAY, and EXTEND operations, and all stream, record, and block operations use the pool specified by the CREATE or OPEN operation that opened the file.

### 3.5 COMPLETION STATUS

A directory or file operation returns a completion status code in the 1-word STS field of the FAB, and a completion status value in the 1-word STV field of the FAB.

### 3.6 DIRECTORY OPERATIONS

RMS-11 directory operations affect only directory entries (not the contents of files). The directory operations are:

- RENAME: replace a directory entry
- PARSE: analyze a file specification
- SEARCH: search directories

The next sections provide an overview of the directory operations (except for the SEARCH operation, which is discussed in Section 3.8).

### 3.6.1 RENAME Operation

Your program can replace the directory entry for a file by using the RENAME operation. The fully qualified file specification for the new directory entry must not specify a new device or directory for the file, but it can specify different file name and file extension elements.

If you do not specify a device, the device associated with the old file specification is used.

For both the old and new directory entries, the RENAME operation uses the device and directory elements of the fully qualified file specification to determine the target directory; it uses the file name and type elements of the fully qualified file specification to identify the entry to be removed or created.

### 3.6.2 PARSE Operation

Your program can use the PARSE operation to analyze a file specification, or to prepare for a series of wildcard operations (described in Section 3.8). The results of the PARSE operation are described in detail in Section 3.3.

## 3.7 FILE OPERATIONS

RMS-11 file operations affect files as whole entities (but not individual records or blocks in files). The file operations are:

- CREATE: create a file (and a corresponding directory entry) and open the file for processing
- OPEN: open an existing file for processing
- DISPLAY: write file information to control blocks
- ERASE: delete file contents (records or blocks) and remove directory entry
- EXTEND: increase the allocation for a file
- CLOSE: close an open file

The next sections discuss file operations.

### 3.7.1 CREATE Operation

The CREATE operation creates a new file and opens it for processing; unless the file is specified as a temporary file, the CREATE operation also creates a directory entry for the file.

The CREATE operation uses the device and directory elements of the fully qualified file specification to determine the target directory; it then uses the file name and type of the fully qualified file specification to form the entry in that directory.

### 3.7.2 OPEN Operation

Your program can establish an access path to a file by using the OPEN operation. This makes file information available to your program, and enables your program to use the following operations for the file:

- DISPLAY operation (to make more file information available to your program).
- EXTEND operation (to allocate more space for the file).
- CONNECT operation (to establish a path to file records or blocks). The CONNECT operation enables your program to use other stream operations and either record operations or block operations.
- CLOSE operation (to release resources committed to the open file). The CLOSE operation terminates the access path established by the CREATE or OPEN operation that opened the file.

### 3.7.3 DISPLAY Operation

If your program uses the OPEN operation to open a file, but does not provide control blocks and buffers for all the information that the OPEN operation can return, you may want to use the DISPLAY operation to obtain additional information while the file is open.

### 3.7.4 ERASE Operation

Your program can erase the contents of a file by using the ERASE operation, and remove its directory entry.

The ERASE operation uses the fully qualified file specification to determine the target file. It uses the device and directory elements of the fully qualified file specification to determine the target directory, and the file name and type elements to determine the entry to be removed.

### 3.7.5 EXTEND Operation

Your program can increase the allocation for an open file by using the EXTEND operation. Note that RMS-11 automatically extends the file allocation when it needs more space; you can use the EXTEND operation to make large extensions (avoiding repeated automatic extensions) or exact extensions (avoiding wasteful automatic extensions).

### 3.7.6 CLOSE Operation

Your program can close an open file by using the CLOSE operation. This releases task and system resources (other than the file itself) and makes those resources available for other uses.

### 3.8 WRITING WILDCARD LOOPS

You can include wildcard characters in an RMS-11 file specification and use the PARSE and SEARCH operations to identify files that match the wildcard specification. This allows you to program a wildcard loop that successively (and selectively, if you wish) processes files matching the wildcard specification.

An advantage of RMS-11 wildcarding over system wildcard commands is that your processing can be selective. For example, if you use a system wildcard command to rename a group of files, the entire group is renamed; if you use a wildcard loop in a program, the program can fully examine information about each file and even the contents of each file to decide whether to rename it.

The next three sections show:

- The structure of a wildcard loop and the behavior of directory and file operations in the loop
- How to write a wildcard loop that nonselectively uses the ERASE or RENAME operation on successive matching files
- How to write a wildcard loop that selectively performs directory and file operations on successive matching files

#### 3.8.1 Introduction to Wildcarding

This discussion assumes that you want to write a program loop that uses a wildcard input file specification, and that you want to use the same control blocks (FAB and NAM block) for all operations associated with the wildcard loop.

A series of wildcard operations can be viewed as having four steps:

1. Initializing for wildcarding
2. Finding the next matching file
3. Operating on the found file
4. Ending wildcarding

The next sections discuss these steps.

**3.8.1.1 Initializing for Wildcarding** - The PARSE operation initializes control blocks (FAB and NAM block) for wildcard operations. Place the \$PARSE macro before the wildcard loop in your program.

The PARSE operation sets the NB\$WCH mask in the 1-word FNB field of the NAM block to show that wildcard operations are in progress. (Your program must clear the NB\$WCH mask if it will not perform SEARCH operations after a PARSE operation.)

The PARSE operation also forms a match-pattern in the expanded string buffer (whose address is in the 1-word ESA field of the NAM block); this match-pattern is used by subsequent wildcard SEARCH operations.

## PROCESSING DIRECTORIES AND FILES

A series of SEARCH operations requires a NAM block that specifies both expanded string and resultant string buffers. (The resultant string buffer is specified in the l-word RSA field of the NAM block.) Your program must not alter the expanded string, the resultant string, or other NAM block contents between the PARSE operation and the end of the subsequent series of SEARCH operations.

**3.8.1.2 Finding the Next Matching File** - The SEARCH operation finds the next file (if any) that matches the wildcard input file specification. (If the SEARCH operation cannot find another matching file, wildcarding ends; see Section 3.8.1.4.)

The SEARCH operation returns a fully qualified file specification in the resultant string buffer, along with the device identifier for the found file. The file identifier is returned also if the FB\$FID mask in the l-word FOP field of the FAB is set.

The SEARCH operation in your wildcard loop can either be explicit (your loop contains the \$SEARCH macro) or, for some operations, implicit (RMS-11 automatically performs the SEARCH operation). If you use the explicit SEARCH operation, place the \$SEARCH macro inside the loop but before other operation macros.

If you use an ERASE or RENAME (old FAB) operation in the loop with the FB\$FID mask in the l-word FOP field of the FAB cleared, RMS-11 implicitly performs a SEARCH operation (to find the next matching file) before performing the ERASE or RENAME operation. This allows your wildcard loop to omit the \$SEARCH macro. (If the implicit SEARCH operation cannot find another matching file, wildcarding ends; see Section 3.8.1.4.)

**3.8.1.3 Operating on the Found File** - A number of directory and file operations are wildcard-transparent in the sense that they preserve both wildcard context information and information about the last-found file. This means that your program can use the operations within a wildcard loop without changing the wildcard context; the series of wildcard operations is continuable.

These wildcard-transparent operations are: CLOSE, DISPLAY, and EXTEND, and (if the FB\$FID mask in the l-word FOP field of the FAB is set) ERASE, OPEN, and RENAME (old FAB).

**3.8.1.4 Ending Wildcarding** - A series of wildcard operations (using a specific FAB and NAM block) ends when a directory or file operation discards wildcard context information or when your program clears the NB\$WCH mask in the l-word FNB field of the NAM block.

Typically, the operation that ends wildcarding is a SEARCH operation that cannot find another matching file. It returns the ER\$NMF completion status code and clears the NB\$WCH mask in the l-word FNB field of the NAM block.

If your program exits from a wildcard loop before the SEARCH operation fails to find a matching file, the NB\$WCH mask in the l-word FNB field of the NAM block is still set, and your program must clear it.

Executing the PARSE operation during a wildcard series ends that series and initializes control blocks for a new series.

Executing a CREATE operation or executing an OPEN operation with the FB\$FID mask in the 1-word FOP field of the FAB cleared, ends the wildcard series for that FAB.

### 3.8.2 Nonselective ERASE or RENAME Wildcard Operations

You can write a wildcard loop that performs nonselective ERASE or RENAME operations on successive matching files, where RMS-11 implicitly performs a SEARCH operation before each ERASE or RENAME operation.

To do this, do the following:

1. Use the PARSE operation to initialize control block fields for wildcarding.
2. Clear the FB\$FID mask in the 1-word FOP field of the FAB (for the RENAME operation, the old FAB). This causes the ERASE or RENAME operation to perform an implicit SEARCH operation before performing its own processing.
3. Use the ERASE or RENAME operation to operate on the next matching file.
4. Examine the STS field of the FAB. If it contains the ER\$NMF completion status code, there was not another matching file; in that case, go to step 7.
5. Perform other in-loop processing (such as reporting the file specification of the erased, removed, or renamed file).
6. Go to step 2.
7. The wildcard series is finished; continue with other processing.

The following program segment illustrates this procedure, performing the ERASE operation. In the program segment, FABADR is a label giving the address of the FAB for the operations, and R0 is used (for the \$STORE and \$COMPARE macros) to contain the address of the FAB.

```

                $PARSE      #FABADR          ;Set up for wildcarding
LOOP:          MOV         #FABADR,R0       ;FAB address to R0
                $OFF       #FB$FID,FOP,R0 ;Use implicit search
                ;         ; (FB$FID off)
                $ERASE     #FABADR         ;Try to erase next file
                $COMPARE   #ER$NMF,STS,R0 ;Was there a matching file?
                BEQ        DONE            ;No more matching files
                . . .                    ;Other in-loop processing
                BR         LOOP            ;On to next matching file

DONE:         . . .                      ;Continue with other
                ;         ; processing

```

## 3.8.3 Selective Wildcard Operations

You can write a wildcard loop that performs directory and file operations on selected matching files, where your program explicitly performs a SEARCH operation at the beginning of each iteration of the loop. To do this, do the following:

1. Use the PARSE operation to initialize control block fields for wildcarding.
2. Use the SEARCH operation to obtain information about the next file that matches the wildcard specification.
3. Examine the STS field of the FAB. If it contains the ER\$NMF completion status code, there was not another matching file; in that case, go to step 6.
4. Perform directory and file operations on the found file. If ERASE, OPEN, or RENAME operations are included, be sure the FB\$FID mask in the l-word FOP field of the FAB (for the RENAME operation, the old FAB) is set.

Do not perform CREATE or PARSE operations, or OPEN operations with the FB\$FID mask cleared; these operations end wildcarding.

Do not perform ERASE or RENAME operations with the FB\$FID mask cleared; these operations perform an implicit SEARCH operation, advancing to the next matching file.

5. Go to step 2.
6. The wildcard series is finished; continue with other processing.

The following program segment illustrates the procedure, performing the ERASE operation on selected files. In the program segment, FABADR is a label giving the address of the FAB for the operations, and R0 is used (for the \$COMPARE macro) to contain the address of the FAB.

```

                $PARSE      #FABADR          ;Set up for wildcarding

LOOP:   $SEARCH      #FABADR          ;Find next matching file
        MOV          #FABADR,R0       ;FAB address to R0
        $COMPARE    #ER$NMF,STS,R0    ;Any more matching files?
        BEQ         DONE             ;No more matching files
        . . .                       ;Decide whether to delete
                                        ; file (if so, Z-bit on)
        BNE         NOOP             ;Don't delete file
        MOV          #FABADR,R0       ;FAB address to R0
        $SET        #FB$FID,FOP,R0    ;Explicit SEARCH already done
        $ERASE      #FABADR          ;Erase file contents
NOOP:   . . .                       ;Other in-loop processing
        BR          LOOP             ;On to next matching file

DONE:   . . .                       ;Continue with other
                                        ; processing

```

## CHAPTER 4

### PROCESSING RECORDS AND BLOCKS

This chapter describes use of RMS-11 stream, record, and block operations; its major sections are:

- Completion status
- Streams
- Record processing
- Block processing

#### 4.1 COMPLETION STATUS

A stream, record, or block operation returns a completion status code in the 1-word STS field of the RAB; it may also return a completion status value in the 1-word STV field of the RAB.

#### 4.2 STREAMS

A stream is a path from your program to the data in a file. The CONNECT operation establishes a stream; for the CREATE or OPEN operation that opened the file, your program specified either record access or block access.

If it specified record access, the stream is a record stream and supports only stream operations and record operations; if it specified block access, the stream is a block stream and supports only stream operations and block operations.

For the CONNECT operation, your program specifies the FAB for the file (in the 1-word FAB field of the RAB), and the CONNECT operation returns an internal stream identifier (in the 1-word ISI field of the RAB). All stream, block, and record operations (except CONNECT) identify the file using the internal stream identifier; the DISCONNECT operation terminates the stream, and clears the internal stream identifier.

### 4.3 RECORD PROCESSING

This section describes use of RMS-11 record processing. Its subsections are:

- Record streams: the paths from your program to file records
- Record context: the "current location" of a stream in a file
- Record access modes: the ways your program can access records
- Record buffers: the locations of records in your program's space
- Locate mode: a way of speeding record processing
- Stream operations: stream operations for a record stream
- Record operations: operations that access records

#### 4.3.1 Record Streams

A record stream is a path from your program to the records in a file. Your program establishes a record stream when it uses the CONNECT operation to connect a stream to a file (opened for record access by an earlier CREATE or OPEN operation). A record stream supports stream operations and record operations, but not block operations.

If the target file for a stream is a relative or indexed file, your program can establish more than one stream for the file; if, in addition, your program specifies access sharing, more than one task can establish streams for the file.

#### 4.3.2 Record Context

A record stream has a record context, which consists of a current-record context and a next-record context. Some record operations use the current record or next record as the target for the operation; some stream and record operations change the current-record context, the next-record context, or both.

The notion of "following record" is important to record context because the next-record context is often established as the record "following" the current record. The precise meaning of "following record" depends on the file organization:

- In a sequential file, the record following a given record is the one immediately following it in physical sequence.
- In a relative file, the record following a given record is the one in the first higher-numbered cell that contains a record.
- In an indexed file, a record follows another only with respect to an index; each index imposes an order on the file records. The record following a given record (under a given index) is the record whose record key is the smallest in the file that is greater than the record key of the given record; among records having identical record keys, a record written later follows a record written earlier.

Note that although an operation may establish the next-record context, that context is not evaluated until another operation uses it. For example, if your program connects a stream to a relative file that contains records only in cells 5 and 10, a sequential access GET operation returns the record in cell 5 and establishes both current-record and next-record context; if another stream or task then inserts a record in cell 7 before your program executes a second sequential access GET operation, that GET operation returns the new record (cell 7), even though the record did not exist when the next-record context was established.

#### 4.3.3 Record Access Modes

The record operations FIND, GET, and PUT allow your program to specify a record access mode (in the 1-byte RAC field of the RAB); the record access mode determines the target record for the operation. The record access modes are:

- Sequential access
- Key access
- RFA access

The next sections discuss these access modes.

**4.3.3.1 Sequential Access** - Your program specifies sequential access by setting the RB\$SEQ code in the 1-byte RAC field of the RAB. A sequential access FIND or GET operation has as its target the next record. (Exception: a sequential access GET operation that immediately follows any FIND operation has as its target the current record, which is the record found by the FIND operation.)

The target of a sequential access PUT operation depends on the file organization, as follows:

- For a sequential file, a series of sequential access put operations must begin with the next-record context at the end-of-file. The series of PUT operations adds new records at the end-of-file.
- For a relative file, a series of sequential access PUT operations must begin with the next-record context set such that the first cell examined is empty (unless the RB\$UIF mask in the 1-word ROP field of the RAB is set). The series of PUT operations adds new records in successive cells; if a nonempty cell is encountered, the PUT operation returns the ER\$REX completion (unless the RB\$UIF mask is set, in which case the existing record is overwritten).
- For an indexed file, a series of sequential access PUT operations does not depend on the next-record context; however, a PUT operation in the series returns the ER\$SEQ completion if the value of the record primary key for the operation is less than the value of the record primary key for the preceding PUT operation.

## PROCESSING RECORDS AND BLOCKS

A sequential access FIND or GET operation sets the current-record context to the target record, and sets the next-record context to the record following the target record. Sequential access PUT operations leave both the current-record and next-record contexts undefined.

This targeting and context setting means, generally speaking, that a series of sequential access operations operates on successive records. Specifically, series of sequential access operations result as follows:

- A series of sequential access FIND operations sets the stream context to successive records.
- A series of sequential access GET operations reads successive records.
- A series of sequential access PUT operations writes successive records (for an indexed file, possibly interspersed with existing records).
- A series of paired sequential access FIND and sequential access GET operations reads successive records.

**4.3.3.2 Key Access** - Your program specifies key access by setting the RB\$KEY code in the 1-byte RAC field of the RAB. A key access FIND, GET, or PUT operation has as its target the record that your program specifies by specifying the key. For a relative file or for a sequential disk file with fixed-length records, your program specifies the key as a relative record number. Specify the relative record number in the 1-word KBF field of the RAB and the key size as 0 or 4 in the 1-byte KSZ field of the RAB.

For a FIND or GET operation for an indexed file, your program specifies the index of reference and a key buffer that contains the record key. Specify the index of reference in the 1-byte KRF field of the RAB, the address of the key buffer in the 1-word KBF field of the RAB, and the key size in the 1-byte KSZ field of the RAB.

A key access FIND or GET operation sets the current-record context to the record that is the target of the operation; a key access PUT operation leaves the current-record context undefined.

A key access FIND or PUT operation does not affect the next-record context; a key access GET operation sets the next-record context to the record following the target record.

The target of a key access FIND, GET, or PUT operation depends on the operation and on the file organization:

- For a relative file or for a sequential disk file with fixed-length records, the key is a positive integer and specifies the position of the record in the file. This key is the relative record number (RRN) for the record; RRN 1 specifies the first record, and so forth.

If your program sets the RB\$KGT mask in the 1-word ROP field of the RAB, a FIND or GET operation searches for a record whose RRN is greater than the given RRN; if it sets the RB\$KGE mask in the 1-word ROP field of the RAB, the operation searches for a record whose RRN is greater than or equal to the given RRN; if it sets neither of these masks, the operation searches for a record with the given RRN.

Note that a FIND, GET, or PUT operation to a relative file or to a sequential disk file with fixed length records returns the RRN for the target record in the 2-word BKT field of the RAB.

- For a FIND or GET operation to an indexed file, the key specifies a record in the file whose record key matches the given key. Your program specifies both the key to be matched and the file index; the key data type must agree with the key data type for the index (string, packed decimal, binary, or signed integer).

For a string key, your program specifies the portion of the key that must be matched. If the value in the 1-byte KSZ field of the RAB is nonzero but is smaller than the record key, then only that smaller initial portion of the key must match.

If your program sets the RB\$KGT mask in the 1-word ROP field of the RAB, a FIND or GET operation searches for a record whose key is greater than the given key; if it sets the RB\$KGE mask in the 1-word ROP field of the RAB, the operation searches for a record whose key is greater than or equal to the given key; if it sets neither of these masks, the operation searches for a record whose key exactly matches the given key.

- For a PUT operation to an indexed file, the key (for each index) is in the record. The operation has no true target; the record is inserted at the proper place and each index is updated.

This targeting and context setting means that although the target of the key access operation is a random (selected) record, the record context allows subsequent sequential access processing. Therefore your program can use key access to "jump" to a selected point in a file, then use sequential access to process successive records.

**4.3.3.3 RFA Access** - Your program specifies RFA access by setting the RB\$RFA code in the 1-byte RAC field of the RAB. An RFA access FIND or GET operation has as its target the record that your program specifies by RFA (record file address). (The FIND, GET, and PUT operations return the RFA for the target record; if your program saves the RFA, it can use RFA access for the record in subsequent FIND and GET operations.) Specify the RFA in the 3-word RFA field of the RAB.

An RFA access FIND or GET operation sets the current-record context to the record that is the target of the operation. An RFA access FIND operation does not affect the next-record context; an RFA access GET operation set the next-record context to the record following the target record.

This targeting and context setting means that although the target of the RFA access operation is a random (selected) record, the record context allows subsequent sequential access processing. Therefore your program can use RFA access to "jump" to a selected point in a file, then use sequential access to process successive records.

#### 4.3.4 Record Buffers

A PUT or UPDATE operation transfers a record from a record buffer (in your program's space) to a file; for a VFC record, the operation also transfers the fixed-length portion of the record from a separate record header buffer. Your program specifies the address of the record buffer in the 1-word RBF field of the RAB and the size of the record in the 1-word RSZ field of the RAB; for a VFC record, your program also specifies the address of the record header buffer in the 1-word RHB field of the RAB.

A GET operation transfers a record from a file to an RMS-11 internal I/O buffer and to a user buffer in your program's space. Your program specifies the address of the user buffer in the 1-word UBF field of the RAB and its size in the 1-word USZ field of the RAB. Along with the record, the GET operation returns the address of the record in the 1-word RBF field of the RAB and its size in the 1-word RSZ field of the RAB.

For a VFC record, a GET operation also transfers the fixed-length portion of the record to a separate record header buffer in your program's space. Your program specifies the address of the record header buffer in the 1-word RHB field of the RAB.

**Exception:** if your program specifies locate mode for a GET operation, RMS-11 may not transfer the record to the user buffer; see the next section for a discussion of locate mode.

#### 4.3.5 Locate Mode

The GET and PUT operations normally use RMS-11 internal I/O buffers as intermediate storage between your program's buffers (record or user buffers) and the file. By specifying locate mode for a GET or PUT operation, your program requests RMS-11 to transfer records only between its I/O buffers and the file, thus saving time. Your program specifies locate mode by setting the RB\$LOC mask in the 1-word ROP field of the RAB.

If your program specifies locate mode for a GET operation, RMS-11 may transfer the record only to its internal I/O buffer (but not to the user buffer). The GET operation routine decides whether to honor the locate-mode request or to transfer the record to the user buffer anyway; the operation returns the address and size of the retrieved record (informing your program of the record's location -- the user buffer or the I/O buffer).

If your program specifies locate mode for a PUT operation, RMS-11 recognizes that the record may already be in its I/O buffer and if so transfers it to the file from there.

Your program has (in the 1-word RBF field of the RAB) the address of a location (in the I/O buffer if possible, otherwise in the user buffer) that is suitable for building the next record; this address is returned either by a previous locate-mode PUT operation or by an initial locate-mode CONNECT operation. Therefore, if you use the CONNECT operation for a stream that will use locate-mode PUT operations, your program must specify locate mode for the CONNECT operation, and must specify a user buffer (the address in the 1-word UBF field of the RAB and the size in the 1-word USZ field of the RAB).

Note that specifying locate mode for a PUT operation has no effect unless the file is sequential, the access mode is sequential, and the record format is other than stream record format.

#### 4.3.6 Stream Operations

Stream operations affect stream context and I/O buffers (but not file records). The stream operations for a record stream are:

- CONNECT: establish a record stream
- FLUSH: write unwritten buffers for a stream
- FREE: free locked bucket for a stream
- REWIND: set stream context to beginning of current file
- DISCONNECT: terminate a record stream

The next sections discuss these operations.

**4.3.6.1 CONNECT Operation** - Your program uses the CONNECT operation to establish a record stream. (The stream is a record stream because your program specified record access for the CREATE or OPEN operation for the file.)

The current-record context after a CONNECT operation is undefined; the next-record context is (by default) the first record in the file.

For an indexed file, your program must specify an initial index of reference so that the record context is initialized properly.

For a sequential file, your program can specify that the initial record context is to be at the end-of-file (instead of the beginning of the file); in that case, the next-record context after the operation is the end-of-file.

For a sequential disk file, your program specifies the number of blocks in the I/O buffer for the stream; for a relative or indexed file, your program specifies the number of I/O buffers for the stream.

If the stream will use locate-mode PUT operations, your program must also specify locate mode and supply a user buffer. The CONNECT operation returns the address of a location suitable for building the first record to be output; see Section 4.3.5.

**4.3.6.2 FLUSH Operation** - Your program can use the FLUSH operation to write any unwritten buffers for a stream (for example, to increase data integrity by ensuring that all changes have been written to the file); the FLUSH operation does not affect record context, except that the current-record context is undefined for a following TRUNCATE or UPDATE operation to a sequential file.

Note one special case: if the file was opened for deferred writing, but not for write sharing, then the buffer may be controlled by another record stream and will not be written by the FLUSH operation.

**4.3.6.3 FREE Operation** - Your program can use the FREE operation to free a locked bucket for a stream; the FREE operation does not affect stream context, except that the current-record context is undefined for a following DELETE, TRUNCATE, or UPDATE operation.

## PROCESSING RECORDS AND BLOCKS

**4.3.6.4 REWIND Operation** - Your program can use the REWIND operation to reset the context for a stream to the beginning-of-file (the file must not be on a magtape device).

The current-record context after the operation is undefined; the next-record context is the first record in the file; for an indexed file, your program specifies the index of reference for the operation so that the stream context is initialized properly.

**4.3.6.5 DISCONNECT Operation** - Your program can use the DISCONNECT operation to terminate a record stream, thus recovering the resources committed for the stream (primarily pool space). The DISCONNECT operation also discards record context and the internal stream identifier.

### 4.3.7 Record Operations

Record operations affect stream context, buffers (I/O, user, and record), and file records. The record operations are:

- FIND: transfer a record from a file to an I/O buffer
- GET: transfer a record from a file to an I/O buffer and to a user buffer
- PUT: transfer a record from a user buffer to a file
- DELETE: remove a record from a file
- UPDATE: replace a record in a file
- TRUNCATE: remove the current record and all following records from a sequential file

The next sections discuss these operations.

**4.3.7.1 FIND Operation** - Your program can use the FIND operation to transfer a record (or part of a record) from a file to an I/O buffer; the FIND operation does not transfer the record to a user buffer.

Your program specifies an access mode (sequential, key, or RFA) for the FIND operation; Section 4.3.3 describes the target record and context-setting for the FIND operation (Section 4.3.3.1 for sequential access, 4.3.3.2 for key access, and 4.3.3.3 for RFA access).

For a relative file or for a sequential disk file with fixed-length records, the FIND operation returns the relative record number (RRN) and the record file address (RFA) for the found record; for other files, the FIND operation returns only the RFA for the found record.

**4.3.7.2 GET Operation** - Your program can use the GET operation to transfer a record from a file to an I/O buffer and to a user buffer (which your program specifies).

Your program specifies an access mode (sequential, key, or RFA) for the GET operation; Section 4.3.3 describes the target record and context-setting for the GET operation (Section 4.3.3.1 for sequential access, 4.3.3.2 for key access, and 4.3.3.3 for RFA access).

The GET operation returns the address and size of the retrieved record, along with its RFA; for a relative file or for a sequential disk file with fixed-length records, the GET operation also returns the RRN for the retrieved record.

If your program specifies locate mode for the GET operation, it must also specify a user buffer; see Section 4.3.5.

**4.3.7.3 PUT Operation** - Your program can use the PUT operation to transfer a record from a user buffer to an I/O buffer and to a file.

Your program specifies an access mode (sequential or key) for the PUT operation; Section 4.3.3 describes the target record and context-setting for the PUT operation (Section 4.3.3.1 for sequential access, 4.3.3.2 for key access).

Your program can specify that RMS-11 must honor bucket fill numbers.

For an indexed file, your program can specify that each PUT operation in a series is part of a mass insertion; for a relative file, your program can specify that the PUT operation should overwrite the target record (if any).

The PUT operation returns the RFA for the inserted record; for a relative file or for a sequential disk file with fixed-length records, the PUT operation also returns the RRN for the inserted record.

If your program specifies locate mode for the PUT operation, it must also specify a user buffer. The PUT operation returns the address of a location suitable for building the next output record; see Section 4.3.5.

**4.3.7.4 DELETE Operation** - Your program can use the DELETE operation to remove a record from a relative or indexed file. The target of a DELETE operation is the current record.

The current-record context after a DELETE operation is undefined; the next-record context is unchanged.

For an indexed file, your program can specify that RMS-11 must use the fast-deletion procedure. However, this procedure is faster because it deletes only those alternate index pointers that it must; future retrieval operations may be slowed by the presence of undeleted alternate index pointers.

**4.3.7.5 UPDATE Operation** - Your program can use the UPDATE operation to transfer a record from a user buffer to a file (overwriting the existing record). The target of the UPDATE operation is the current record, which is overwritten.

## PROCESSING RECORDS AND BLOCKS

The current-record context after an UPDATE operation is undefined; the next-record context is unchanged.

Your program specifies the record buffer for the record to be inserted (and, for a VFC record, the VFC-header buffer).

**4.3.7.6 TRUNCATE Operation** - Your program can use the TRUNCATE operation to remove the current record and all following records (through the end-of-file) from a sequential file. The current-record context after a TRUNCATE operation is undefined; the next-record context is the new end-of-file.

### 4.4 BLOCK PROCESSING

This section describes use of RMS-11 block processing. Its subsections are:

- Block streams: the paths from your program to file blocks
- Block context: the "current location" of a stream in a file
- Block access modes: the ways your program can access blocks
- Block buffers: the locations of blocks in your program's space
- Stream operations: stream operations for a block stream
- Block operations: operations that access blocks

#### 4.4.1 Block Streams

A block stream is a path from your program to the blocks in a file. Your program establishes a block stream when it uses the CONNECT operation to connect a stream to a file (opened for block access by an earlier CREATE or OPEN operation). A block stream supports stream operations and block operations, but not record operations.

#### 4.4.2 Block Context

A block stream has a block context, which consists of a readable-block context and a writable-block context. The READ operation uses the readable-block as its target block; the WRITE operation uses the writable-block as its target block; block operations change both the readable-block and the writable-block contexts.

For a disk file, your program can use the READ or WRITE operation to read or write multiple blocks in a single operation. In that case, reading or writing begins at the readable block or the writable block (respectively), and continues through the number of blocks requested.

#### 4.4.3 Block Access Modes

The block operations READ and WRITE allow your program to specify a block access mode (in the 2-word BKT field of the RAB); the block access mode determines the target block for the operation. The block access modes are:

- Sequential access
- VBN access

For a magtape file, your program can use either sequential block access or VBN access; however, the program must access one block at a time, and in sequential order.

The next sections discuss these access modes.

**4.4.3.1 Sequential Access** - Your program specifies sequential block access by giving the value 0 in the 2-word BKT field of the RAB. A sequential access READ operation has as its target the readable block; it sets the readable-block context to the next-following unread block, and sets the writable-block context to the target block (first block read for that READ operation).

A sequential access WRITE operation has as its target the writable block; it sets both the readable-block and writable-block contexts to the next-following unwritten block.

This targeting and context setting has the following results:

- A series of sequential access READ operations reads successive blocks.
- A series of sequential access WRITE operations writes successive blocks.
- A series of paired READ and WRITE operations updates successive blocks.

**4.4.3.2 VBN Access** - A VBN access READ or WRITE operation reads or writes blocks beginning with a virtual block that your program specifies. Specify the virtual block number in the 2-word BKT field of the RAB.

Note that your program can use VBN access to move to a random position in a disk file, and then use sequential block access to process blocks sequentially from that point.

#### 4.4.4 Block Buffers

Your program specifies a user buffer for the READ operation; the operation returns the address of the first-read byte and the number of bytes read. Specify the address of the user buffer in the 1-word UBF field of the RAB and its size in the 1-word USZ field of the RAB; the READ operation returns the address of the first-read byte in the 1-word RBF field of the RAB and the number of bytes read in the 1-word RSZ field of the RAB.

## PROCESSING RECORDS AND BLOCKS

Your program specifies the buffer containing the writable data for the WRITE operation. Specify the buffer address in the 1-word RBF field of the RAB and its size in the 1-word RSZ field of the RAB.

### 4.4.5 Stream Operations

Stream operations affect stream context and I/O buffers (but not file blocks). The stream operations for a block stream are:

- CONNECT: establish a block stream
- FREE: free a locked block for a stream
- DISCONNECT: terminate a block stream

The next sections discuss these operations.

**4.4.5.1 CONNECT Operation** - Your program uses the CONNECT operation to establish a block stream. (The stream is a block stream because your program specified block access for the CREATE or OPEN operation for the file.)

After a CONNECT operation, both the readable-block and writable-block contexts are the first block in the file.

**4.4.5.2 FREE Operation** - Your program can use the FREE operation to free a locked block for a stream; the FREE operation does not affect stream context.

**4.4.5.3 DISCONNECT Operation** - Your program can use the DISCONNECT operation to terminate a block stream, thus recovering the resources committed for the stream. The DISCONNECT operation also discards block context and the internal stream identifier.

### 4.4.6 Block Operations

Block operations affect stream context, block buffers, and file blocks. The block operations are:

- READ: transfer blocks from a file to a block buffer
- WRITE: transfer blocks from a block buffer to a file

The next sections discuss these operations.

**4.4.6.1 READ Operation** - Your program can use the READ operation to transfer blocks from a file to a block buffer. Your program specifies an access mode (sequential or VBN) for the READ operation; Section 4.4.3.1 describes sequential access; Section 4.4.3.2 describes VBN access.

**4.4.6.2 WRITE Operation** - Your program can use the WRITE operation to transfer blocks from a block buffer to a file. Your program specifies an access mode (sequential or VBN) for the WRITE operation; Section 4.4.3.1 describes sequential access; Section 4.4.3.2 describes VBN access.

Note that because the WRITE operation always writes to the file immediately, the FLUSH operation has no use for block access.

## CHAPTER 5

### OPERATION MACRO DESCRIPTIONS

This chapter describes RMS-11 operation macros and the operation routines they call. Each section of the chapter describes an operation macro and its corresponding operation. (For the \$FIND, \$GET, \$PUT, \$READ, and \$WRITE macros, there is a separate description for each access method.)

Each description is divided into the following parts:

- **FORMAT** - the format for the macro and its parameters
- **CONTROL BLOCKS** - the required and optional control blocks for the operation
- **OPTIONS** - the options that you can select for the operation, and the control block fields and values that control the options
- **STREAM CONTEXT** - the current-record and next-record contexts (for a record stream) or the readable-block and writable-block contexts (for a block stream) after the operation completes
- **RETURNED VALUES** - the values that the operation routine returns in control block fields and buffers
- **CHECKLISTS** - a list of the control block fields that you supply to specify options, and a list of the control block fields that contain returned values

The operation macros are:

- **\$CLOSE** - Close an open file
- **\$CONNECT** - Connect a record stream to an open file
- **\$CREATE** - Create a new file and open it for processing
- **\$DELETE** - Remove a record from a file
- **\$DISCONNECT** - Disconnect a record stream
- **\$DISPLAY** - Write file data into control block fields
- **\$ERASE** - Erase an existing file
- **\$EXTEND** - Extend the allocation for an open file
- **\$FIND** - Set the stream context to a record in a file
- **\$FLUSH** - Write any unwritten buffers for a stream

## OPERATION MACRO DESCRIPTIONS

- \$FREE - Unlock a bucket locked by a stream
- \$GET - Retrieve a record from a file
- \$OPEN - Open an existing file
- \$PARSE - Write file data into a NAM block
- \$PUT - Insert a record into a file
- \$READ - Read blocks from a file
- \$RENAME - Rename an existing file
- \$REWIND - Set stream context to beginning-of-file
- \$SEARCH - Search directories for a file specification
- \$TRUNCATE - Remove all following records from a file
- \$UPDATE - Replace a record in a file
- \$WRITE - Write blocks into a file

## 5.1 \$CLOSE MACRO

The \$CLOSE macro calls the CLOSE operation routine to close an open file.

### FORMAT

The format for the \$CLOSE is:

```
$CLOSE fabaddr[, [erraddr][, sucaddr]]
```

where fabaddr is the address of the FAB for the operation; erraddr is the address of the error handler for the operation; and sucaddr is the address of the success handler for the operation.

### CONTROL BLOCKS

You must supply a FAB for the CLOSE operation.

To supply XABs (ALL, DAT, KEY, PRO, and SUM blocks) for the CLOSE operation, specify the address of the first XAB in the 1-word XAB field of the FAB; specify the address of the next XAB (if any) in the 1-word NXT field of each XAB; specify 0 in the NXT field of the last XAB.

All KEY blocks must be together in the chain of XABs, and must be in ascending order (by the index reference number in the 1-byte REF field of the KEY block); the index reference numbers need not be consecutive.

All ALL blocks must be together in the chain of XABs, and must be in ascending order (by the area identifier in the 1-byte AID field of the ALL block); the area identifiers need not be consecutive.

Multiple DAT, PRO, or SUM XABs are illegal.

### OPTIONS

#### Internal File Identifier

The CLOSE operation reads the internal file identifier for the file from the 1-word IFI field of the FAB. This identifier was written by the CREATE or OPEN operation when the file was opened.

#### Rewinding Magtape

For a magtape file, if you want the magtape rewound when the file is closed, set the FB\$RWC mask in the 1-word FOP field of the FAB. Note that if the FB\$RWC mask was set when the file was opened (by the CREATE or OPEN operation), setting the mask has no effect for the CLOSE operation.

### STREAM CONTEXT

The CLOSE operation destroys stream context for any streams connected by the closing file (after writing any unwritten buffers for those streams).

OPERATION MACRO DESCRIPTIONS  
\$CLOSE MACRO

RETURNED VALUES

Private Buffer Pool

The CLOSE operation writes the address of the private buffer pool (if any) for the file in the 1-word BPA field of the FAB; if the CLOSE operation clears the BPA field, the file had no private buffer pool.

If the file had a private buffer pool, the CLOSE operation writes the size (in bytes) of the pool in the 1-word BPS field of the FAB, or clears this field if the file did not use a private buffer pool.

Internal File Identifier

The CLOSE operation clears the 1-word IFI field of the FAB.

Completion Status and Value

The CLOSE operation returns completion status in the 1-word STS field of the FAB and returns a completion value in the 1-word STV field of the FAB. Appendix A lists completion status symbols and values.

CHECKLISTS

Table 5-1 lists control block fields that are input to the CLOSE operation. Table 5-2 lists control block fields that are output by the CLOSE operation.

Table 5-1: CLOSE Input Fields

Block Field	Description
ALL AID	Area number
ALL NXT	Next XAB address
DAT NXT	Next XAB address
FAB FOP	File processing option mask
	FB\$RWC Rewind magtape after closing file
FAB IFI	Internal file identifier
FAB XAB	XAB address
KEY REF	Index reference number
KEY NXT	Next XAB address
PRO NXT	Next XAB address
SUM NXT	Next XAB address

Table 5-2: CLOSE Output Fields

Block Field	Description
FAB BPA	Private buffer pool address
FAB BPS	Private buffer pool size (bytes)
FAB IFI	Internal file identifier
FAB STS	Completion status code
FAB STV	Completion status value

## 5.2 \$CONNECT MACRO

The \$CONNECT macro calls the CONNECT operation routine to connect a record stream to an open file, and initialize the stream context.

### FORMAT

The format for the \$CONNECT is:

```
$CONNECT rabaddr[, [erraddr] [, sucaddr]]
```

where rabaddr is the address of the RAB for the operation; erraddr is the address of the error handler for the operation; and sucaddr is the address of the success handler for the operation.

### CONTROL BLOCKS

You must supply a RAB for the CONNECT operation.

You must supply a FAB for the CONNECT operation.

### OPTIONS

#### File Identification

Specify the address of the FAB in the 1-word FAB field of the RAB. The CONNECT operation reads the internal file identifier for the file from the 1-word IFI field of the FAB.

#### I/O Buffers

For a sequential disk file, specify the size (in blocks) of the RMS-11 I/O buffer for the stream in the 1-byte MBC field of the RAB; the largest legal value is 63. If you specify 0, the CONNECT operation uses a buffer of one block. For a relative file, an indexed file, or a sequential nondisk file, the CONNECT operation ignores the MBC field.

For a relative or indexed file, specify the number of I/O buffers for the stream in the 1-byte MBF field of the RAB. For a sequential file, specify 0 in the MBF field. If you specify 0, the CONNECT operation uses the minimum number of buffers: one for a sequential or relative file, or two for an indexed file.

#### User Buffer (Locate Mode for Sequential File)

If you are connecting to a sequential file, and if you intend to execute PUT operations in locate mode for the connected stream, then:

- Specify the address of the user buffer in the 1-word UBF field of the RAB.
- Specify the size (in bytes) of the user buffer in the 1-word USZ field of the RAB.
- Set the RB\$LOC mask in the 1-word ROP field of the RAB.

**OPERATION MACRO DESCRIPTIONS**  
**\$CONNECT MACRO**

This assures proper handling of the first PUT operation for the stream.

**Key of Reference (Indexed File)**

For an indexed file, specify the key of reference in the 1-byte KRF field of the RAB. This value specifies the index to be used in establishing initial record context: 0 for the primary index, 1 for the first alternate index, and so forth.

**Initial Stream Context (Sequential File)**

If you want to initialize the next-record context of a sequential file to the end-of-file, set the RB\$EOF mask in the 1-word ROP field of the RAB; if you do not set this mask, the CONNECT operation initializes the next-record context to the first record in the file (or to the end-of-file if the file is empty).

**STREAM CONTEXT**

For a record-access file, the current-record context after a CONNECT operation is undefined; the next-record context is the first record in the file (under the specified index for an indexed file), or the end-of-file, if the file is empty.

For a block-access file, both the readable-block and writable-block contexts after a CONNECT operation are the first block in the file.

**RETURNED VALUES**

**Internal Stream Identifier**

The CONNECT operation writes an internal stream identifier in the 1-word ISI field of the RAB. Do not destroy this identifier; all other stream, record, and block operation routines read it.

**Record Buffer**

The CONNECT operation copies the value from the UBF field into the 1-word RBF field of the RAB (the record address); this prepares the record buffer for your use in case the first record operation for the stream is a locate-mode PUT operation to a sequential file.

**RFA**

For block access, the CONNECT operation returns the logical end-of-file value in the 3-word RFA field of the RAB. The first two words of this field are the VBN in which the logical end-of-file occurs, and the third word is the offset of the first byte beyond the logical end-of-file within that block. This logical end-of-file value is meaningful only for disk files.

**Completion Status and Value**

The CONNECT operation returns completion status in the 1-word STS field of the RAB and returns a completion value in the 1-word STV field of the RAB. Appendix A lists completion status symbols and values.

**CHECKLISTS**

Table 5-3 lists control block fields that are input to the CONNECT operation. Table 5-4 lists control block fields that are output by the CONNECT operation.

**Table 5-3: CONNECT Input Fields**

Block Field	Description
FAB IFI	Internal file identifier
RAB FAB	FAB address
RAB KRF	Key of reference
RAB MBC	Multiblock count
RAB MBF	Multibuffer count
RAB ROP	Record processing option mask
	RB\$EOF Position to end-of-file
	RB\$LOC Locate mode
RAB UBF	User buffer address
RAB USZ	User buffer size (bytes)

**Table 5-4: CONNECT Output Fields**

Block Field	Description
RAB ISI	Internal stream identifier
RAB RBF	Record buffer address
RAB RFA	End-of-file address
RAB STS	Completion status code
RAB STV	Completion status value

OPERATION MACRO DESCRIPTIONS  
\$CREATE MACRO

5.3 \$CREATE MACRO

The \$CREATE macro calls the CREATE operation routine to create a new file and open it for processing.

FORMAT

The format for the \$CREATE is:

```
$CREATE fabaddr[, [erraddr][, sucaddr]]
```

where fabaddr is the address of the FAB for the operation; erraddr is the address of the error handler for the operation; and sucaddr is the address of the success handler for the operation.

CONTROL BLOCKS

You must supply a FAB for the CREATE operation.

If you supply a NAM block, the CREATE operation reads its fields to obtain the expanded string buffer, and writes identifiers in its fields.

To supply a NAM block for the CREATE operation, specify the address of the NAM block in the 1-word NAM field of the FAB.

Each ALL block that you supply defines one area in the created file, and (for area 0) you can place the area at a specific location. If you supply no ALL blocks, the file has one area; you define this area in the FAB, but you cannot place the area at a specific location. You cannot supply more than one ALL block for a sequential or relative file.

Each KEY block that you supply defines one index for the created file. You must supply at least one KEY block for an indexed file; you cannot supply KEY blocks for a relative or sequential file.

If you supply a PRO block, the CREATE operation reads its fields to obtain the protection for the file.

To supply XABs (ALL, DAT, KEY, PRO, and SUM blocks) for the CREATE operation, specify the address of the first XAB in the 1-word XAB field of the FAB; specify the address of the next XAB (if any) in the 1-word NXT field of each XAB; specify 0 in the NXT field of the last XAB.

All KEY blocks must be together in the chain of XABs, and must be in ascending order (by the index reference number in the 1-byte REF field of the KEY block); the index reference numbers must be consecutive beginning with 0.

All ALL blocks must be together in the chain of XABs, and must be in ascending order (by the area identifier in the 1-byte AID field of the ALL block); the area identifiers must be consecutive beginning with 0.

Multiple DAT, PRO, or SUM XABs are illegal.

Note that if the LAN field of a KEY XAB is 0, RMS-11 will use the area specified in the IAN field for the lowest level index for that index.

## OPTIONS

### File Specification

The CREATE operation constructs the full file specification from the file string, the default string (which contributes only elements not present in the file string), and RMS-11 defaults (which contribute elements not present in either the file string or the default string).

RMS-11 defaults are:

- Device -- The device to which the specified logical channel is assigned, or SY: if the specified logical channel is not assigned to any device.
- Directory -- The current directory for the task.
- Name, type, -- Defaulted to null.

The file string and the default string must not contain wildcards.

Specify the address of the file string in the 1-word FNA field of the FAB. Specify the size (in bytes) of the file string in the 1-byte FNS field of the FAB; if you specify 0 in the FNS field, the CREATE operation uses no file string.

Specify the address of the default string in the 1-word DNA field of the FAB. Specify the size (in bytes) of the default string in the 1-byte DNS field of the FAB; if you specify 0 in the DNS field, the CREATE operation uses no default string.

If you set the FB\$FID mask in the 1-word FOP field of the FAB and supply a NAM block, the CREATE operation reads the device identifier from the 2-word DVI field of the NAM block; if this value is nonzero, the specified device overrides the device in the merged string.

### Expanded String Buffer

If you want the CREATE operation to return the expanded string for the created file, provide a buffer for the string. Specify the address of the expanded string buffer in the 1-word ESA field of the NAM block and its size (in bytes) in the 1-byte ESS field of the NAM block; if you specify 0 in the ESS field, the CREATE operation does not return the expanded string.

### Supersession of Existing File

If you want to create a file that supersedes an existing file with the same specification, set the FB\$SUP mask in the 1-word FOP field of the FAB; if you do not set the FB\$SUP mask, and you specify a file that already exists, the CREATE operation returns an error completion and does not create the new file.

### Temporary or Marked-for-Delete File

If you want the created file to be a temporary file (one that will be deleted as part of the logout procedure), set the FB\$TMP mask in the 1-word FOP field of the FAB.

## OPERATION MACRO DESCRIPTIONS

### \$CREATE MACRO

Regardless of any name you may specify, the temporary file will be created with the name TEMPnn.TMP, where nn is the job number.

Note that when you use several temporary files, there will be only one visible temporary file. Each temporary file created will supersede any existing temporary file of the same name, and such superseded files will be marked for deletion (and deleted when closed).

If you want the created file to be deleted when it is closed, set the FB\$MKD mask in the 1-word FOP field of the FAB; this causes the operating system to delete the file when it has no accessing programs. If you do not set the FB\$MKD mask, the created file is not marked for deletion.

If you want the created file to be a temporary file that is marked for deletion, set the FB\$TMD mask in the 1-word FOP field of the FAB; the FB\$TMD mask includes the bits for both the FB\$TMP and the FB\$MKD masks.

### File Protection

Specify the protection for the created file in the 1-word PRO field of the PRO block; if you supply no PRO block, the operating system uses its default file protection.

Protection codes are 1 byte long and range from 0 to 255:

- A word value between 0 and 255 will explicitly set the protection code.
- A word value of -1 will set the code as the user's default, unless a protection specification is included in the file specification (this code will override the user's default).
- A word value of -2 will override the protection code set in the file specification and set the code as the user's default, ignoring any protection specification that may have been included in the file specification.

### File Organization

Specify a file organization code in the 1-byte ORG field of the FAB. The symbols for file organization codes are:

FB\$IDX Indexed file organization  
FB\$REL Relative file organization  
FB\$SEQ Sequential file organization

### Record Format

Specify the record format code in the 1-byte RFM field of the FAB. The symbols for record format codes are:

FB\$FIX Fixed-length record format  
FB\$STM Stream record format  
FB\$UDF Undefined record format  
FB\$VAR Variable-length record format  
FB\$VFC VFC record format

If you specify VFC record format (FB\$VFC code in the RFM field), specify the size (in bytes) of the VFC header field in the 1-byte FSZ field of the FAB; if you specify 0, the CREATE operation uses the value 2.

### Blocked Records

If you are creating a sequential disk file, and if you want the file to contain blocked records (records that cannot span block boundaries), set the FB\$BLK mask in the 1-byte RAT field of the FAB; if you do not set the FB\$BLK mask, records can span block boundaries.

If you are creating a relative or indexed file, the FB\$BLK mask has no effect on storage of records in the file. However, this mask will be preserved and returned on OPEN operations. The FB\$BLK mask is ignored for files on unit-record devices.

Note that records are always blocked in a magtape file, regardless of the FB\$BLK setting.

### Record-Output Handling

Specify a record-output mask in the 1-byte RAT field of the FAB. This record-output attribute controls the handling of records that are output to a unit-record device:

- FORTRAN-style record-output specifies FORTRAN-style carriage-control handling.
- Carriage-return record-output specifies that a prefixed linefeed and a suffixed carriage-return must be added to each record on output to a print device.
- Print-format record-output specifies that the file is in print format. This format is allowed only for files with VFC records for which the fixed header size for each record is 0 or 2 bytes. (RMS-11 treats a header size of 0 as if you had specified 2.)

When records from the file are written directly to a unit-record device, RMS-11 interprets the first byte of the VFC header as a prefix for the record and the second byte of the header as a suffix for the record. RMS-11 further interprets the prefix/suffix control bytes as follows:

If the top bit of the control byte is clear, the entire byte is used as a count of the number of carriage return/line feed pairs with which to prefix or suffix the record.

If the top bit of the control byte is set, the low 5 bits of the byte are used as the prefix or suffix character.

If you specify none of these attributes, records are output to unit-record devices without special handling.

If you are creating a file on a device other than a unit-record device, the record output mask has no effect on storage of records in the file. However, this mask will be preserved and returned on OPEN operations.

**OPERATION MACRO DESCRIPTIONS**  
**\$CREATE MACRO**

The symbols for record-output masks are:

FB\$CR	Add CRLF to print record (LF-record-CR)
FB\$FTN	FORTTRAN-style carriage-control character in record
FB\$PRN	VFC print record handling

**Record Size**

Specify the record size (in bytes) in the 1-word MRS field of the FAB (unless you have specified undefined record format). For fixed-length records, the CREATE operation uses this value as the record size; for variable-length records, the CREATE operation uses this value as the maximum record size; for VFC records, the CREATE operation uses this value as the maximum size of the variable portion of each record.

If you specify a nonzero value in the MRS field, RMS-11 checks the size of each record written to the file against the MRS-field value, and returns an error completion if the record size is inappropriate; if you specify 0 in the MRS field, RMS-11 does not check record sizes against the MRS-field value.

**Maximum Record Number**

If you specify relative file organization (FB\$REL value in the ORG field), specify the maximum record number in the 2-word MRN field of the FAB. If you specify a nonzero value in the MRN field, RMS-11 checks the record number of each record written to the file against the MRN-field value, and returns an error completion if the record number is too large; if you specify 0 in the MRN field, RMS-11 does not check record numbers against the MRN-field value.

**Cluster Size**

Specify the cluster size (in blocks) for the file in the 1-byte RTV field of the FAB. If you specify 0, the CREATE operation uses the cluster size for the volume; if you specify -1, the CREATE operation uses the value 256; if you specify any other value, the value must be a power of 2, and must be at least as large as the volume cluster size.

**Private Buffer Pool**

If you want the CREATE operation to use a private buffer pool instead of the central buffer pool, specify the address of the (word-aligned) private buffer pool in the 1-word BPA field of the FAB, and its size (in bytes) in the 1-word BPS field of the FAB; this size must be a multiple of 4.

If you specify 0 in either the BPA field or the BPS field, the CREATE operation uses the central buffer pool.

The pool that the CREATE operation uses is also used by the DISPLAY and EXTEND operations, and by stream and record operations while the file is open.

### Logical Channel

Specify the logical channel for the CREATE operation in the 1-byte LCH field of the FAB. The logical channel number must not be the same as the logical channel number for any already-open file, and must not be 0.

The logical channel that the CREATE operation uses is also used by the DISPLAY and EXTEND operations, and by stream and record or block operations while the file is open.

### Requested Access

Specify one or more requested-access masks in the 1-byte FAC field of the FAB. This mask determines the access that the creating program has while the file is open. Regardless of what you specify, the CREATE operation includes the mask FB\$PUT (for record access) or FB\$WRT (for block access). The symbols for requested-access masks are:

FB\$DEL	Request find/get/delete access
FB\$GET	Request find/get access
FB\$PUT	Request put access
FB\$REA	Request block read access
FB\$TRN	Request find/get/truncate access
FB\$UPD	Request find/get/update access
FB\$WRT	Request block write access

Note that FB\$REA and FB\$WRT override any record access requested.

### Access Sharing

Specify the kinds of access that your program is willing to share with other programs by setting an access-sharing mask in the 1-byte SHR field of the FAB. The symbols for access-sharing masks are:

FB\$GET	Share find/get access
FB\$NIL	No access sharing
FB\$WRI	Share find/get/put/update/delete access

The kinds of access sharing are:

- **Shared read access**

Your program is willing to allow other programs to read the file, but not to write it.

Even if your program specifies shared read access, other programs will be unable to read (or write) the file if your program requests any form of write access (which is always the case for CREATE).

- **Shared write access**

Your program is willing to allow other programs to both read and write the file. Shared write access is not allowed for a sequential file unless the file has undefined record format and your program opens the file for block access; shared write access is also not allowed for a relative or indexed file that your program opens for block access. In such cases, RMS-11 automatically converts the shared write access specification to a shared read access specification internally.

**OPERATION MACRO DESCRIPTIONS**  
**\$CREATE MACRO**

- **No shared access**

Your program is not willing to allow other programs to either read or write the file. RMS-11 does, however, allow other programs to read the file unless your program also requests some form of write access (which is always the case for CREATE).

### **Deferred Writing**

If you want deferred buffer writing for the open file, set the FB\$DFW mask in the 1-word FOP field of the FAB; This means that RMS-11 does not necessarily write its buffers during a write-type operation (DELETE, PUT, or UPDATE), but instead writes buffers only when it needs them for other operations (or when your program executes the FLUSH operation for the stream).

If you do not set the FB\$DFW mask, the DELETE, PUT, and UPDATE operations write buffers to the file immediately.

Note that record operations always use a form of deferred buffer writing for sequential files, and that block operations never use deferred buffer writing. Therefore you need only decide whether to use deferred writing for a record stream to a relative or indexed file.

### **Magtape Block Size**

If you are creating a magtape file, specify the block size (in characters) for the file in the 1-word BLS field of the FAB. If you specify 0, RMS-11 uses the default block size for the device.

### **Magtape Positioning**

You can position a magtape file on its magtape. To position the file at the beginning of the magtape (overwriting all files on the tape), set the FB\$RWO mask in the 1-word FOP field of the FAB. To position the file at the end of the last-closed file (overwriting any following files), set the FB\$POS mask in the 1-word FOP field of the FAB. If you set neither of these masks, the CREATE operation positions the file at the end of the last file on the magtape (overwriting nothing).

### **Rewinding Magtape on Close**

If you want the magtape rewound when the created file is closed, set the FB\$RWC mask in the 1-word FOP field of the FAB. If you do not set this mask, the magtape will not be rewound on close unless you set the FB\$RWC mask for the CLOSE operation. Note, however, that if you set the FB\$RWC mask for the CREATE operation, the magtape will be rewound even if you do not set the FB\$RWC mask for the CLOSE operation.

### Single-Area Unlocated File

If you want the created file to have only one area, and if you do not want to place the area at a specific location on disk, then you supply no ALL blocks for the CREATE operation, but rather specify the following file attributes in FAB fields (as described in sections below):

- File allocation size
- Default file extension size
- File bucket size
- File contiguity

### Multiarea or Located File

If you want to place the created file at a specific location on disk, or if you want a created indexed file to have more than one area, then you supply ALL blocks for the CREATE operation and you specify the following area attributes in ALL block fields (as described in sections below):

- Area allocation size
- Default area extension size
- Area bucket size
- Area contiguity
- Area alignment
- Area location

Specify the area number for each area in the 1-byte AID field of the ALL block for the area.

Sequential and relative files are permitted to have only a single area: area 0. Thus, for these files, the information in the (single) ALL block describes the file as a whole, overriding any corresponding information in the FAB.

Similarly, block-accessed indexed files are treated without regard for their internal (logical) structure. In this case, only a single ALL block is permitted, and its contents describe the file as a whole, overriding any corresponding information in the FAB.

Symmetric treatment of ALL blocks by the OPEN operation facilitates block-access COPY operations, which are independent of file organization.

### Allocation Size

For a single-area unlocated file, specify the file allocation size (in blocks) in the 2-word ALQ field of the FAB. For a multiarea or located file, specify the area allocation size (in blocks) in the 2-word ALQ field of the ALL block for each area.

OPERATION MACRO DESCRIPTIONS  
\$CREATE MACRO

**Default Extension Size**

For a single-area unlocated file, specify the default extension size (in blocks) for the file in the 1-word DEQ field of the FAB. For a multiarea or located file, specify the default extension size (in blocks) for each area in the 1-word DEQ field of the ALL block for the area.

**Bucket Size (Relative or Indexed File)**

For a single-area unlocated file, specify the bucket size (in blocks) for the file in the 1-byte BKS field of the FAB. For a multiarea or located file, specify the bucket size (in blocks) for each area in the 1-byte BKZ field of the ALL block for the area.

The largest allowed bucket size is 15 blocks; the smallest is 0. If you specify a bucket size of 0, the CREATE operation uses 1-block buckets for the file or area.

**Area Location**

If you want to place area 0 at a particular cluster on disk, specify the XB\$LBN mask in the 1-byte ALN field of the ALL block for area 0. If you do not specify this mask, the CREATE operation places area 0 at any convenient location.

Specify the number of the cluster in the 2-word LOC field of the ALL block for area 0.

The CREATE operation creates areas by extending the file if either of the following is true:

- You specify placement for areas other than area 0 (in which case the CREATE operation ignores the FB\$CTG mask).
- You specify contiguity in one or more ALL blocks, but not in the FAB for the file.

Otherwise the CREATE operation creates the entire file as a single operation, and, if you specified contiguity in the FAB, creates the entire file as a single contiguous extent.

**Contiguity**

If you want a file to be contiguous, set the FB\$CTG mask in the 1-word FOP field of the FAB and (for a multiarea file) do not specify disk location for any area except (optionally) area 0; if the CREATE operation cannot create a contiguous file, it returns an error completion; if you do not set this mask, the CREATE operation does not attempt to create a contiguous file.

If you want area 0 of a multiarea or located file to be contiguous, set the XB\$CTG mask in the 1-byte AOP field of the ALL block for area 0. If you set this mask and the CREATE operation cannot create a contiguous area 0, it returns an error completion; if you do not set this mask, the CREATE operation does not attempt to create a contiguous area.

## Indexes

If you specify indexed file organization (FB\$IDX value in the ORG field), you must supply at least one KEY block for the CREATE operation, unless you are using block access (in which case, any KEY blocks are ignored). Each KEY block you supply defines one index for the created file.

Specify the reference number for each index in the 1-byte REF field of the KEY block for the index. Specify 0 for the primary index, 1 for the first alternate index, and so forth. Chain KEY blocks so that the reference numbers are in consecutive order, and so that there are no intervening XABS of other types (ALL, DAT, PRO, or SUM blocks).

## Key Name

If you want to define a key name for the index, place the key name string in a 32-character buffer. Specify the address of this buffer in the 1-word KNM field of the KEY block for the index. If you specify 0 in the KNM field, the index has no key name.

## Index Key Data Type

Specify a key data type code in the 1-byte DTP field of the KEY block for each index. The symbols for key data type codes are:

XB\$BN2	16-bit unsigned integer
XB\$BN4	32-bit unsigned integer
XB\$IN2	15-bit signed integer
XB\$IN4	31-bit signed integer
XB\$PAC	Packed decimal number
XB\$STG	String

## Key Segments

Specify the size and position of each key segment in the 8-byte SIZ field of the KEY block and the 8-word POS field of the KEY block for the index. (Only a string key can have more than one segment.)

The first byte of the SIZ field is for the size (in bytes) of the first key segment, the second byte is for the second segment, and so forth. If the key is to have fewer than eight segments, specify 0 in the remaining bytes of the SIZ field. (The CREATE operation does not check segment sizes after the first 0 it encounters in the SIZ field.)

The first word of the POS field is for the position of the first key segment, the second word is for the second segment, and so forth. If the key has fewer than eight segments, the CREATE operation ignores the remaining words of the POS field. (The first position in a record is position 0.)

## Key Changes

For an alternate index, if you want to allow the key to change during update operations, set the XB\$CHG mask in the 1-byte FLG field of the KEY block and the XB\$DUP mask in the 1-byte FLG field of the KEY block for the index; if you do not set these masks, RMS-11 returns an error if a program attempts to change the value of a record key during updating.

**OPERATION MACRO DESCRIPTIONS**  
**\$CREATE MACRO**

**Key Duplications**

If you want to allow duplicate keys in an index, set the XB\$DUP mask in the 1-byte FLG field of the KEY block for the index. If you do not set this mask, RMS-11 returns an error if a program attempts to insert or update a record that would create a duplicate record key. Note that the XB\$DUP mask must be set if record keys in the index are to be changeable during update.

**Null Keys**

If you want to omit null keys from an alternate index, set the XB\$NUL mask in the 1-byte FLG field of the KEY block for the index, and (for a string key) specify the null character for the key in the 1-byte NUL field of the KEY block (the null value for a nonstring key is 0).

If you do not set the XB\$NUL mask, all keys are included in the index; if you set the XB\$NUL mask, a nonstring key with a 0 value or a string key with an all-null value will not appear in that alternate index.

**Index Areas**

Specify areas for the data records and for the levels of the index:

- The area for data records in the 1-byte DAN field of the KEY block
- The area for the lowest index level in the 1-byte LAN field of the KEY block
- The area for higher index levels in the 1-byte IAN field of the KEY block

Note that the bucket sizes of the LAN and IAN areas of a given index must be identical.

**Bucket Fill Numbers**

Bucket fill numbers guide the PUT and UPDATE operations in deciding how many records to place in each bucket. A bucket fill number of 0 is usually appropriate, and specifies that buckets should be filled completely.

A nonzero bucket fill number specifies the number of bytes that should be filled in each bucket. If the specified bucket fill number is less than half the bucket size, it is rounded up to half the bucket size; if the specified number is more than the bucket size, it is rounded down to the bucket size.

Specify the fill numbers for data buckets and index buckets: the fill number for data buckets in the 1-word DFL field of the KEY block, and the fill number for index buckets in the 1-word IFL field of the KEY block.

**Longest Record Length**

If you specify block access for the created file, and you plan to copy an existing file into the new file, you can specify the length of the longest record in the new file in the 1-word LRL field of the FAB.

## RETURNED VALUES

### Internal File Identifier

The CREATE operation writes an internal file identifier in the 1-word IFI field of the FAB. (The CLOSE operation clears the internal file identifier.)

The CLOSE, CONNECT, DISPLAY, and EXTEND operations read the internal file identifier; do not alter the IFI field while the file is open.

### Device Characteristics

The CREATE operation returns device characteristics as masks in the 1-byte DEV field of the FAB. The device characteristics are:

- Printer or terminal (indicated by the set FB\$CCL mask in the 1-byte DEV field of the FAB and the set FB\$REC mask in the 1-byte DEV field of the FAB; for a terminal, the FB\$TRM mask in the 1-byte DEV field of the FAB is also set); RMS-11 treats a printer or terminal as a unit-record device.
- Disk, DEctape, or DECTAPE II (indicated by the set FB\$MDI mask in the 1-byte DEV field of the FAB); RMS-11 treats a disk, DEctape, or DECTAPE II as a disk device.
- Unit-record device (indicated by the set FB\$REC mask in the 1-byte DEV field of the FAB).
- Non-ANSI magtape or cassette tape (indicated by the set FB\$SDI mask in the 1-byte DEV field of the FAB and the set FB\$REC mask in the 1-byte DEV field of the FAB); RMS-11 treats a non-ANSI magtape or a cassette tape as a unit-record device.
- ANSI-format magtape (indicated by the set FB\$SQD mask in the 1-byte DEV field of the FAB).

### Device and File Identifiers

If you supply a NAM block, the CREATE operation writes a device identifier in the 2-word DVI field of the NAM block, and a file identifier in the 3-word FID field of the NAM block.

### Expanded String

If you specify a buffer for the expanded string for the file (ESA and ESS fields in the NAM block), the CREATE operation writes the file specification for the created file in this buffer, and writes the length (in bytes) of the specification string in the 1-byte ESL field of the NAM block.

**OPERATION MACRO DESCRIPTIONS**  
**\$CREATE MACRO**

**File Specification Characteristics**

The CREATE operation sets masks in the 1-word FNB field of the NAM block to show which file specification elements were present in the file string and default string. These masks and their meanings are:

NB\$NOD	Node in file string or default string
NB\$DEV	Device in file string or default string
NB\$DIR	Directory in file string or default string
NB\$QUO	Quoted string in file string or default string
NB\$NAM	File name in file string or default string
NB\$TYP	File type in file string or default string
NB\$VER	File version in file string or default string
NB\$WDI	Wildcard directory in file string or default string
NB\$WNA	Wildcard file name in file string or default string
NB\$WTY	Wildcard file type in file string or default string
NB\$WVE	Wildcard file version in file string or default string

**Wildcarding**

The CREATE operation clears the NB\$WCH mask in the 1-word FNB field of the NAM block; this shows that no wildcard context exists after the CREATE operation. It also clears the 1-byte RSL field of the NAM block to show that no resultant string was returned.

**Extension Sizes**

The CREATE operation returns the size (in blocks) of each allocation it makes. If you created only area 0 using FAB fields, the CREATE operation writes the size of the allocation in the 2-word ALQ field of the FAB. If you created areas using ALL blocks, the CREATE operation writes the size of each area allocation in the 2-word ALQ field of the ALL block for the area.

**Completion Status and Value**

The CREATE operation returns completion status in the 1-word STS field of the FAB and returns a completion value in the 1-word STV field of the FAB. Appendix A lists completion status symbols and values.

**CHECKLISTS**

Table 5-5 lists control block fields that are input to the CREATE operation. Table 5-6 lists control block fields that are output by the CREATE operation.

Table 5-5: CREATE Input Fields

Block	Field	Description
ALL	AID	Area number
ALL	ALN	Initial area alignment request
		XB\$LBN Cluster alignment
ALL	ALQ	Initial area allocation request size (blocks)
ALL	AOP	Area option mask
		XB\$CTG Contiguous area request
ALL	BKZ	Area bucket size (blocks)
ALL	DEQ	Area default extension size (blocks)
ALL	LOC	Initial area location request
ALL	NXT	Next XAB address
DAT	NXT	Next XAB address
FAB	ALQ	Initial file allocation request size (blocks)
FAB	BKS	File bucket size (blocks)
FAB	BLS	Magtape block size (characters)
FAB	BPA	Private buffer pool address
FAB	BPS	Private buffer pool size (bytes)
FAB	DEQ	Permanent file default extension size (blocks)
FAB	DNA	Default string address
FAB	DNS	Default string size (bytes)
FAB	FAC	Requested access mask
		FB\$DEL Request find/get/delete access
		FB\$GET Request find/get access
		FB\$PUT Request put access
		FB\$REA Request block read access
		FB\$TRN Request find/get/truncate access
		FB\$UPD Request find/get/update access
		FB\$WRT Request block write access
FAB	FNA	File string address
FAB	FNS	File string size (bytes)
FAB	FOP	File processing option mask
		FB\$CTG Contiguous file request
		FB\$DFW Defer writing
		FB\$FID Use information in NAM block
		FB\$MKD Mark file for deletion
		FB\$POS Position magtape after last-closed file
		FB\$RWC Rewind magtape after closing file
		FB\$RWO Rewind magtape before creating file
		FB\$SUP Supersede existing file
		FB\$TMD Temporary file, mark for deletion
		FB\$TMP Temporary file
FAB	FSZ	Fixed control area size for VFC records (bytes)
FAB	LCH	Logical channel number
FAB	LRL	Longest record length
FAB	MRN	Maximum record number
FAB	MRS	Maximum record size (bytes)

(Continued on next page)

Table 5-5 (Cont.): CREATE Input Fields

Block	Field	Description
FAB	NAM	NAM block address
FAB	ORG	File organization code
		FB\$IDX Indexed file organization
		FB\$REL Relative file organization
		FB\$SEQ Sequential file organization
FAB	RAT	Record handling mask
		FB\$BLK Blocked records
		FB\$CR Add CRLF to print record (LF-record-CR)
		FB\$FTN FORTRAN-style carriage-control character in record
		FB\$PRN VFC print record handling
FAB	RFM	Record format code
		FB\$FIX Fixed-length record format
		FB\$STM Stream record format
		FB\$UDF Undefined record format
		FB\$VAR Variable-length record format
		FB\$VFC VFC record format
FAB	RTV	Cluster size (blocks)
FAB	SHR	Shared access mask
		FB\$GET Share find/get access
		FB\$NIL No access sharing
		FB\$WRI Share find/get/put/update/delete access
FAB	XAB	XAB address
KEY	DAN	Data area number
KEY	DFL	Data bucket fill factor
KEY	DTP	Key data type code
		XB\$BN2 16-bit unsigned integer
		XB\$BN4 32-bit unsigned integer
		XB\$IN2 15-bit signed integer
		XB\$IN4 31-bit signed integer
		XB\$PAC Packed decimal number
		XB\$STG String
KEY	FLG	Index option mask
		XB\$DUP Duplicate record keys allowed
		XB\$CHG Record key changes allowed on update
		XB\$NUL Null record keys not indexed
KEY	IAN	Higher level index area number
KEY	IFL	Index bucket fill factor
KEY	KNM	Key name buffer address
KEY	LAN	Lowest index level area number
KEY	NUL	Null key character
KEY	NXT	Next XAB address
KEY	POS	Key segment positions
KEY	REF	Index reference number
KEY	SIZ	Key segment sizes (bytes)

(Continued on next page)

Table 5-5 (Cont.): CREATE Input Fields

Block Field	Description
NAM ESA	Expanded string buffer address
NAM DVI	Device identifier
NAM ESS	Expanded string buffer size (bytes)
PRO NXT	Next XAB address
PRO PRO	File protection code
SUM NXT	Next XAB address

Table 5-6: CREATE Output Fields

Block Field	Description
ALL ALQ	Initial area allocation size (blocks)
FAB ALQ	Initial file allocation size (blocks)
FAB DEV	Device characteristic mask
	FB\$CCL Carriage-control device
	FB\$MDI Multidirectory device
	FB\$REC Record-oriented device

## OPERATION MACRO DESCRIPTIONS

### \$DELETE MACRO

#### 5.4 \$DELETE MACRO

The \$DELETE macro calls the DELETE operation routine to remove a record from a relative or indexed file. The target of the DELETE operation is the current record. The current record must be locked; it was automatically locked when the current-record context was set, but you must not have unlocked it with a FREE operation.

If the stream has no current-record context, or if the current record is not locked, the DELETE operation returns an error completion.

#### FORMAT

The format for the \$DELETE is:

```
$DELETE rabaddr[, [erraddr][, sucaddr]]
```

where rabaddr is the address of the RAB for the operation; erraddr is the address of the error handler for the operation; and sucaddr is the address of the success handler for the operation.

#### CONTROL BLOCKS

You must supply a RAB for the DELETE operation.

#### OPTIONS

##### Internal Stream Identifier

The DELETE operation reads the internal stream identifier from the l-word ISI field of the RAB.

##### Fast Deletion (Indexed File)

If the file is an indexed file, and if its alternate indexes allow duplicate keys, then you can speed up the DELETE operation by using the fast-deletion procedure. However, this procedure is faster because it deletes only those alternate index pointers that it must; future retrieval operations may be slowed by the presence of undeleted alternate index pointers.

To use the fast-deletion procedure with the DELETE operation, set the RB\$FDL mask in the l-word ROP field of the RAB. If you do not set this mask, the DELETE operation does not use the fast-deletion procedure.

#### STREAM CONTEXT

The current-record context after a DELETE operation is undefined; the next-record context is unchanged.

RETURNED VALUES

Completion Status and Value

The DELETE operation returns completion status in the 1-word STS field of the RAB and returns a completion value in the 1-word STV field of the RAB. Appendix A lists completion status symbols and values.

CHECKLISTS

Table 5-7 lists control block fields that are input to the DELETE operation. Table 5-8 lists control block fields that are output by the DELETE operation.

Table 5-7: DELETE Input Fields

Block Field	Description
RAB ISI	Internal stream identifier
RAB ROP	Record processing option mask
	RB\$FDL Fast deletion

Table 5-8: DELETE Output Fields

Block Field	Description
RAB STS	Completion status code
RAB STV	Completion status value

## OPERATION MACRO DESCRIPTIONS

### \$DISCONNECT MACRO

#### 5.5 \$DISCONNECT MACRO

The \$DISCONNECT macro calls the DISCONNECT operation routine to terminate a stream and disconnect it, releasing the internal resources it was using. The stream context is lost; you cannot reestablish the same stream context by reconnecting the stream with the CONNECT operation.

#### FORMAT

The format for the \$DISCONNECT is:

```
$DISCONNECT rabaddr[, [erraddr][, sucaddr]]
```

where rabaddr is the address of the RAB for the operation; erraddr is the address of the error handler for the operation; and sucaddr is the address of the success handler for the operation.

#### CONTROL BLOCKS

You must supply a RAB for the DISCONNECT operation.

#### OPTIONS

##### Internal Stream Identifier

The DISCONNECT operation reads the internal stream identifier from the 1-word ISI field of the RAB.

#### STREAM CONTEXT

The DISCONNECT operation terminates the stream; therefore there is no stream context after the DISCONNECT operation.

#### RETURNED VALUES

##### Internal Stream Identifier (Cleared)

The DISCONNECT operation clears the internal stream identifier from the 1-word ISI field of the RAB.

##### Completion Status and Value

The DISCONNECT operation returns completion status in the 1-word STS field of the RAB and returns a completion value in the 1-word STV field of the RAB. Appendix A lists completion status symbols and values.

#### CHECKLISTS

Table 5-9 lists control block fields that are input to the DISCONNECT operation. Table 5-10 lists control block fields that are output by the DISCONNECT operation.

Table 5-9: DISCONNECT Input Fields

Block	Field	Description
RAB	ISI	Internal stream identifier

Table 5-10: DISCONNECT Output Fields

Block	Field	Description
RAB	ISI	Internal stream identifier
RAB	STS	Completion status code
RAB	STV	Completion status value

OPERATION MACRO DESCRIPTIONS  
\$DISPLAY MACRO

## 5.6 \$DISPLAY MACRO

The \$DISPLAY macro calls the DISPLAY operation routine to write values into control block fields. The DISPLAY operation does not alter the file in any way.

When you use the OPEN operation to open a file, you might not know how many areas or how many indexes the file has. If, however, you supply a SUM block for the OPEN operation, the OPEN operation writes the number of areas and number of keys (indexes) in its fields. You can then supply ALL blocks and KEY blocks so that the DISPLAY operation can fill their fields with values describing the file areas and indexes.

### FORMAT

The format for the \$DISPLAY is:

```
$DISPLAY fabaddr[, [erraddr] [, sucaddr]]
```

where fabaddr is the address of the FAB for the operation; erraddr is the address of the error handler for the operation; and sucaddr is the address of the success handler for the operation.

### CONTROL BLOCKS

You must supply a FAB for the DISPLAY operation.

If the file is an indexed file, for each ALL block that you supply, the DISPLAY operation fills its fields with values describing the corresponding area (if any) of the file. You need not supply an ALL block for every area of the file. Note that if the file was opened for block access, no information is returned in ALL blocks.

For each KEY block that you supply, the DISPLAY operation fills its fields with values describing the corresponding index (if any) for the file. You need not supply a KEY block for every index of the file. Note that if the file was opened for block access, no information is returned in KEY blocks.

If you supply a SUM block for a relative or indexed file, the DISPLAY operation fills its fields with values showing the number of areas and indexes for the file, and with its prologue version number. (If you are opening the file for block access, the DISPLAY operation returns the number of areas and number of keys as 0, and does not return the prologue version number.)

To supply XABs (ALL, DAT, KEY, PRO, and SUM blocks) for the DISPLAY operation, specify the address of the first XAB in the 1-word XAB field of the FAB; specify the address of the next XAB (if any) in the 1-word NXT field of each XAB; specify 0 in the NXT field of the last XAB.

All KEY blocks must be together in the chain of XABs, and must be in ascending order (by the index reference number in the 1-byte REF field of the KEY block); the index reference numbers need not be consecutive.

All ALL blocks must be together in the chain of XABs, and must be in ascending order (by the area identifier in the 1-byte AID field of the ALL block); the area identifiers need not be consecutive.

Multiple DAT, PRO, or SUM XABs are illegal.

**OPTIONS**

**Internal File Identifier**

The DISPLAY operation reads the internal file identifier from the 1-word IFI field of the FAB. This is the value that was written when the file was opened by the CREATE or OPEN operation.

**Key Name Buffer**

If you want the key name string for an index returned to a buffer, supply a KEY block for the index; specify the address of a 32-byte buffer in the 1-word KNM field of the KEY block. If you do not supply a KEY block for an index, or if you specify 0 in its KNM field, the DISPLAY operation does not return the key name string.

**STREAM CONTEXT**

The DISPLAY operation does not affect stream context.

**RETURNED VALUES**

**Area Descriptions**

For each ALL block that you supply, the DISPLAY operation writes a description in its fields of the corresponding area of the file. Area 0 is described in the ALL block containing 0 in its AID field; area 1 is described in the ALL block containing 1 in its AID field; and so forth.

The DISPLAY operation writes three sizes for a file area: the size (in blocks) of the unused portion of the area in the 2-word ALQ field of the ALL block, the default area extension size (in blocks) in the 1-word DEQ field of the ALL block, and the area bucket size (in blocks) in the 1-byte BKZ field of the ALL block.

The DISPLAY operation clears the 1-byte AOP field of the ALL block and the 1-byte ALN field of the ALL block.

**Key Descriptions**

For each KEY block that you supply, the DISPLAY operation writes a description in its fields of the corresponding index of the file. The primary index is described in the KEY block containing 0 in its REF field; the first alternate index is described in the KEY block containing 1 in its REF field; and so forth.

The DISPLAY operation writes the key data type code in the 1-byte DTP field of the KEY block. The symbols for key data type codes are:

XB\$BN2	16-bit unsigned integer
XB\$BN4	32-bit unsigned integer
XB\$IN2	15-bit signed integer
XB\$IN4	31-bit signed integer
XB\$PAC	Packed decimal number
XB\$STG	String

OPERATION MACRO DESCRIPTIONS  
\$DISPLAY MACRO

The DISPLAY operation writes key segment information for the index: the number of key segments in the 1-byte NSG field of the KEY block, and the total key size (sum of segments, in bytes) in the 1-byte TKS field of the KEY block.

The DISPLAY operation writes the sizes of key segments in the 8-byte SIZ field of the KEY block. The size (in bytes) of the first key segment is in the first byte of the SIZ field, the size of the second segment is in the second byte of the SIZ field, and so forth. If the key has fewer than eight segments, the first byte containing 0 indicates the number of key segments.

The DISPLAY operation writes the positions of key segments in the 8-word POS field of the KEY block. The position (leftmost position is 0) of the first key segment is in the first word of the POS field, the position of the second segment is in the second word of the POS field, and so forth. If the key has fewer than eight segments, the remaining words of the POS field contain unpredictable values.

The DISPLAY operation writes a key-characteristics mask in the 1-byte FLG field of the KEY block. The symbols for key-characteristics masks are:

XB\$CHG Record key changes allowed on update  
XB\$DUP Duplicate record keys allowed  
XB\$INI No entries yet made in index  
XB\$NUL Null record keys not indexed

The DISPLAY operation writes the null-key character in the 1-byte NUL field of the KEY block. This character is meaningful only if the XB\$NUL mask in the 1-byte FLG field of the KEY block is set and the DISPLAY operation returns the XB\$STG code in the 1-byte DTP field of the KEY block (indicating a string key).

The DISPLAY operation writes area numbers for the index: the area for the data level in the 1-byte DAN field of the KEY block, the area for the lowest index level in the 1-byte LAN field of the KEY block, and the area for higher index levels in the 1-byte IAN field of the KEY block.

The DISPLAY operation writes bucket fill numbers for the index areas: the fill number for the data area in the 1-word DFL field of the KEY block, and the fill number for the index areas in the 1-word IFL field of the KEY block.

The DISPLAY operation writes bucket sizes for index areas: the data area bucket size (in blocks) in the 1-byte DBS field of the KEY block, and the index area bucket size (in blocks) in the 1-byte IBS field of the KEY block.

The DISPLAY operation writes virtual block numbers for the index areas: the virtual block number for the first data bucket in the 2-word DVB field of the KEY block, and the virtual block number of the root index bucket in the 2-word RVB field of the KEY block.

The DISPLAY operation writes the number of levels in the index (not including the data level) in the 1-byte LVL field of the KEY block.

The DISPLAY operation writes the minimum size (in bytes) of a record that contains the key for the index in the 1-word MRL field of the KEY block.

**File Summary Information**

If you supply a SUM block, the DISPLAY operation writes three values in its fields: the number of file areas in the 1-byte NOA field of the SUM block, the number of file indexes in the 1-byte NOK field of the SUM block, and the prologue version number (for a relative or indexed file) in the 1-word PVN field of the SUM block.

**Completion Status and Value**

The DISPLAY operation returns completion status in the 1-word STS field of the FAB and returns a completion value in the 1-word STV field of the FAB. Appendix A lists completion status symbols and values.

**CHECKLISTS**

Table 5-11 lists control block fields that are input to the DISPLAY operation. Table 5-12 lists control block fields that are output by the DISPLAY operation.

**Table 5-11: DISPLAY Input Fields**

Block Field	Description
ALL AID	Area number
ALL NXT	Next XAB address
DAT NXT	Next XAB address
FAB IFI	Internal file identifier
FAB XAB	XAB address
KEY NXT	Next XAB address
KEY KNM	Key name buffer address
KEY REF	Index reference number
PRO NXT	Next XAB address
SUM NXT	Next XAB address

**Table 5-12: DISPLAY Output Fields**

Block Field	Description
ALL ALN	Area alignment mask (cleared)
ALL ALQ	Unused area allocation size (blocks)
ALL AOP	Area option mask
	XB\$CTG Contiguous area (cleared)
ALL BKZ	Area bucket size (blocks)
ALL DEQ	Area default extension size (blocks)
FAB STS	Completion status code
FAB STV	Completion status value
KEY DAN	Data area number
KEY DBS	Data area bucket size (blocks)
KEY DFL	Data bucket fill factor

(Continued on next page)

Table 5-12 (Cont.): DISPLAY Output Fields

Block	Field	Description
KEY	DTP	Key data type code
		XB\$BN2 16-bit unsigned integer
		XB\$BN4 32-bit unsigned integer
		XB\$IN2 15-bit signed integer
		XB\$IN4 31-bit signed integer
		XB\$PAC Packed decimal number
		XB\$STG String
KEY	DVB	First data bucket virtual block number
KEY	FLG	Index option mask
		XB\$CHG Record key changes allowed on update
		XB\$DUP Duplicate record keys allowed
		XB\$INI No entries yet made in index
		XB\$NUL Null record keys not indexed
KEY	IAN	Higher level index area number
KEY	IBS	Index area bucket size (blocks)
KEY	IFL	Index bucket fill factor
KEY	LAN	Lowest index level area number
KEY	LVL	Number of index levels (not including data level)
KEY	MRL	Minimum length of record containing key (bytes)
KEY	NSG	Key segment count
KEY	NUL	Null key character
KEY	POS	Key segment positions
KEY	RVB	Root index bucket virtual block number
KEY	SIZ	Key segment sizes (bytes)
KEY	TKS	Total key size (sum of key segment sizes) (bytes)
SUM	NOA	Number of areas
SUM	NOK	Number of indexes
SUM	PVN	Prologue version number

## 5.7 \$ERASE MACRO

The \$ERASE macro calls the ERASE operation routine to erase a file and delete its directory entry. Note that erasing a file marks the file for deletion, but does not necessarily erase the file immediately; the file is erased when it has no accessing programs. The allocation for the file is released for use in other files.

### FORMAT

The format for the \$ERASE is:

```
$ERASE fabaddr[, [erraddr][, sucaddr]]
```

where fabaddr is the address of the FAB for the operation; erraddr is the address of the error handler for the operation; and sucaddr is the address of the success handler for the operation.

### CONTROL BLOCKS

You must supply a FAB for the ERASE operation.

If you supply a NAM block and specify wildcarding, the ERASE operation reads the address and length of the expanded string from NAM block fields; if you supply a NAM block and specify erase by NAM block, the ERASE operation reads NAM block fields to obtain identifiers for the target file.

To supply a NAM block for the ERASE operation, specify the address of the NAM block in the 1-word NAM field of the FAB.

To supply XABs (ALL, DAT, KEY, PRO, and SUM blocks) for the ERASE operation, specify the address of the first XAB in the 1-word XAB field of the FAB; specify the address of the next XAB (if any) in the 1-word NXT field of each XAB; specify 0 in the NXT field of the last XAB.

All KEY blocks must be together in the chain of XABs, and must be in ascending order (by the index reference number in the 1-byte REF field of the KEY block); the index reference numbers need not be consecutive.

All ALL blocks must be together in the chain of XABs, and must be in ascending order (by the area identifier in the 1-byte AID field of the ALL block); the area identifiers need not be consecutive.

Multiple DAT, PRO, or SUM XABs are illegal.

### OPTIONS

#### File Specification (Nonwildcard ERASE Operation)

The ERASE operation constructs the full file specification from the file string, the default string (which contributes only elements not present in the file string), and RMS-11 defaults (which contribute elements not present in either the file string or the default string).

## OPERATION MACRO DESCRIPTIONS

### \$ERASE MACRO

RMS-11 defaults are:

- Device -- The device to which the specified logical channel is assigned, or SY: if the specified logical channel is not assigned to any device.
- Directory -- The current directory for the task.
- Name, type, -- Defaulted to null.

The file string and the default string must not contain wildcards.

Specify the address of the file string in the 1-word FNA field of the FAB. Specify the size (in bytes) of the file string in the 1-byte FNS field of the FAB; if you specify 0 in the FNS field, the ERASE operation uses no file string.

Specify the address of the default string in the 1-word DNA field of the FAB. Specify the size (in bytes) of the default string in the 1-byte DNS field of the FAB; if you specify 0 in the DNS field, the ERASE operation uses no default string.

If you set the FB\$FID mask in the 1-word FOP field of the FAB and supply a NAM block, the ERASE operation reads the device identifier from the 2-word DVI field of the NAM block; if this value is nonzero, the specified device overrides the device in the merged string.

In the same circumstance, the ERASE operation reads the file identifier from the 3-word FID field of the NAM block; if this value is nonzero, the specified file overrides any directory, name, and type elements previously obtained.

#### Erase by Wildcard Specification

You can use the ERASE operation in a wildcarding program loop. (The NB\$WCH mask in the 1-word FNB field of the NAM block will already have been set by an earlier PARSE operation.)

If you set the FB\$FID mask in the 1-word FOP field of the FAB, the file found by a previous SEARCH operation and its directory entry are deleted, but all fields relevant to wildcard context are preserved (for possible subsequent SEARCH operations).

If you clear the FB\$FID mask in the 1-word FOP field of the FAB, the ERASE operation first performs an implicit SEARCH operation. (The input and output fields for the SEARCH operation are not described here and are not included in the checklists at the end of this section.)

If the SEARCH operation finds a file that matches the wildcard file specification, the ERASE operation erases its contents and deletes its directory entry; if not, the ERASE operation does not erase the file contents or delete its directory entry, but instead passes control block data from the SEARCH operation (in particular, the ER\$NMF completion status code and the cleared NB\$WCH mask in the 1-word FNB field of the NAM block).

#### Expanded String Buffer

If you erase a file by its file specification, and if you want the ERASE operation to return the expanded string for the erased file, provide a buffer for the string. Specify the address of the expanded string buffer in the 1-word ESA field of the NAM block. Specify the

size (in bytes) of the expanded string buffer in the 1-byte ESS field of the NAM block; if you specify 0 in the ESS field, the ERASE operation does not return the expanded string.

#### Private Buffer Pool

If you want the ERASE operation to use a private buffer pool instead of the central buffer pool, specify the address of the (word-aligned) private buffer pool in the 1-word BPA field of the FAB, and its size (in bytes) in the 1-word BPS field of the FAB; this size must be a multiple of 4.

If you specify 0 in either the BPA field or the BPS field, the ERASE operation uses the central buffer pool.

#### Logical Channel

Specify the logical channel for the ERASE operation in the 1-byte LCH field of the FAB. The logical channel number must not be the same as the logical channel number for any already-open file, and must not be 0.

#### RETURNED VALUES

##### Expanded String

If you specify a buffer for the expanded string for the file (ESA and ESS fields in the NAM block), the ERASE operation writes the expanded string for the erased file in the buffer, and writes the length (in bytes) of the string in the 1-byte ESL field of the NAM block.

##### Device and File Identifiers

If you supply a NAM block, the ERASE operation writes a device identifier in the 2-word DVI field of the NAM block, and a file identifier in the 3-word FID field of the NAM block.

##### Device Characteristics

The ERASE operation returns device characteristics as masks in the 1-byte DEV field of the FAB. The device characteristics are:

- Printer or terminal (indicated by the set FB\$CCL mask in the 1-byte DEV field of the FAB and the set FB\$REC mask in the 1-byte DEV field of the FAB; for a terminal, the FB\$TRM mask in the 1-byte DEV field of the FAB is also set); RMS-11 treats a printer or terminal as a unit-record device.
- Disk, DECTape, or DECTAPE II (indicated by the set FB\$MDI mask in the 1-byte DEV field of the FAB); RMS-11 treats a disk, DECTape, or DECTAPE II as a disk device.
- Unit-record device (indicated by the set FB\$REC mask in the 1-byte DEV field of the FAB).

OPERATION MACRO DESCRIPTIONS  
\$ERASE MACRO

- Non-ANSI magtape or cassette tape (indicated by the set FB\$SDI mask in the 1-byte DEV field of the FAB and the set FB\$REC mask in the 1-byte DEV field of the FAB); RMS-11 treats a non-ANSI magtape or a cassette tape as a unit-record device.
- ANSI-format magtape (indicated by the set FB\$SQD mask in the 1-byte DEV field of the FAB).

**Wildcard Context**

A nonwildcard ERASE operation clears the NB\$WCH mask in the 1-word FNB field of the NAM block and the 1-byte RSL field of the NAM block; this shows that no wildcarding is in progress and that no resultant string was returned.

**File Specification Characteristics**

The ERASE operation sets masks in the 1-word FNB field of the NAM block to show which file specification elements were present in the file string and default string. These masks and their meanings are:

NB\$NOD Node in file string or default string  
NB\$DEV Device in file string or default string  
NB\$DIR Directory in file string or default string  
NB\$QUO Quoted string in file string or default string  
NB\$NAM File name in file string or default string  
NB\$TYP File type in file string or default string  
NB\$VER File version in file string or default string  
NB\$WDI Wildcard directory in file string or default string  
NB\$WNA Wildcard file name in file string or default string  
NB\$WTY Wildcard file type in file string or default string  
NB\$WVE Wildcard file version in file string or default string

**Completion Status and Value**

The ERASE operation returns completion status in the 1-word STS field of the FAB and returns a completion value in the 1-word STV field of the FAB. Appendix A lists completion status symbols and values.

**CHECKLISTS**

Table 5-13 lists control block fields that are input to the ERASE operation. Table 5-14 lists control block fields that are output by the ERASE operation.

Table 5-13: ERASE Input Fields

Block	Field	Description
ALL	NXT	Next XAB address
DAT	NXT	Next XAB address
FAB	BPA	Private buffer pool address
FAB	BPS	Private buffer pool size (bytes)
FAB	DNA	Default string address
FAB	DNS	Default string size (bytes)
FAB	FNA	File string address
FAB	FNS	File string size (bytes)

(Continued on next page)

		NB\$WCH Wildcard context established
NAM	RSL	Resultant string length (bytes)

OPERATION MACRO DESCRIPTIONS  
\$EXTEND MACRO

5.8 \$EXTEND MACRO

The \$EXTEND macro calls the EXTEND operation routine to extend the allocation for an open file.

**FORMAT**

The format for the \$EXTEND is:

```
$EXTEND fabaddr[, [erraddr][, sucaddr]]
```

where fabaddr is the address of the FAB for the operation; erraddr is the address of the error handler for the operation; and sucaddr is the address of the success handler for the operation.

**CONTROL BLOCKS**

You must supply a FAB for the EXTEND operation.

For each ALL block that you supply, the EXTEND operation extends the corresponding area as described in the ALL block. You need not supply an ALL block for an area that you do not want to extend, but each supplied ALL block must correspond to an area in the file; this means that you can supply ALL blocks for areas other than area 0 only for an indexed file opened for record access.

To supply XABs (ALL, DAT, KEY, PRO, and SUM blocks) for the EXTEND operation, specify the address of the first XAB in the 1-word XAB field of the FAB; specify the address of the next XAB (if any) in the 1-word NXT field of each XAB; specify 0 in the NXT field of the last XAB.

All KEY blocks must be together in the chain of XABs, and must be in ascending order (by the index reference number in the 1-byte REF field of the KEY block); the index reference numbers need not be consecutive.

All ALL blocks must be together in the chain of XABs, and must be in ascending order (by the area identifier in the 1-byte AID field of the ALL block); the area identifiers need not be consecutive.

Multiple DAT, PRO, or SUM XABs are illegal.

**OPTIONS**

**Internal File Identifier**

The EXTEND operation reads the internal file identifier from the 1-word IFI field of the FAB. This is the value written by the CREATE or OPEN operation that opened the file.

**Area 0 Extended by FAB**

If you supply no ALL blocks, specify the size (in blocks) of the extension in the 2-word ALQ field of the FAB.

**Areas Extended by ALL Blocks**

If you supply ALL blocks, the EXTEND operation ignores the ALQ field of the FAB, and extends each area specified in an ALL block. Specify each area to be extended by supplying an ALL block with the area number in the 1-byte AID field of the ALL block. Specify the size of the extension (in blocks) for the area in the 2-word ALQ field of the ALL block.

**STREAM CONTEXT**

The EXTEND operation does not affect stream context.

**RETURNED VALUES**

**Extension Sizes**

The EXTEND operation returns the size (in blocks) of each extension it makes. If you extended only area 0 using FAB fields, the EXTEND operation writes the size of the extension in the 2-word ALQ field of the FAB. If you extended areas using ALL blocks, the EXTEND operation writes the size of each area extension in the 2-word ALQ field of the ALL block for the area.

**Completion Status and Value**

The EXTEND operation returns completion status in the 1-word STS field of the FAB and returns a completion value in the 1-word STV field of the FAB. Appendix A lists completion status symbols and values.

**CHECKLISTS**

Table 5-15 lists control block fields that are input to the EXTEND operation. Table 5-16 lists control block fields that are output by the EXTEND operation.

**Table 5-15: EXTEND Input Fields**

Block	Field	Description
ALL	AID	Area number
ALL	ALN	Area extension alignment request
ALL	ALQ	Area allocation extension request size (blocks)
ALL	NXT	Next XAB address
DAT	NXT	Next XAB address
FAB	ALQ	File allocation extension request size (blocks)
FAB	IFI	Internal file identifier
FAB	XAB	XAB address
KEY	NXT	Next XAB address
PRO	NXT	Next XAB address
KEY	REF	Index reference number
SUM	NXT	Next XAB address

Table 5-16: EXTEND Output Fields

Block	Field	Description
ALL	ALQ	Area allocation extension actual size (blocks)
FAB	ALQ	File allocation extension actual size (blocks)
FAB	STS	Completion status code
FAB	STV	Completion status value

### 5.9 \$FIND MACRO (SEQUENTIAL ACCESS)

The \$FIND macro calls the FIND operation routine to transfer a record (or part of a record) from a file to an I/O buffer. The FIND operation transfers the entire record if the file is relative or indexed, or if it has blocked records; it may transfer only part of the record if the record spans block boundaries. The FIND operation does not transfer the record to a user buffer.

The target of a sequential-access FIND operation is the next record (for an indexed file, the next record under the current index).

#### FORMAT

The format for the \$FIND is:

```
$FIND rabaddr[, [erraddr] [, sucaddr]]
```

where rabaddr is the address of the RAB for the operation; erraddr is the address of the error handler for the operation; and sucaddr is the address of the success handler for the operation.

#### CONTROL BLOCKS

You must supply a RAB for the FIND operation.

#### OPTIONS

##### Internal Stream Identifier

The FIND operation reads the internal stream identifier from the 1-word ISI field of the RAB.

##### Sequential Access

Specify the RB\$SEQ code in the 1-byte RAC field of the RAB.

#### STREAM CONTEXT

The current-record context after a sequential access FIND operation is the found record; the next-record context is the record following the found record (for an indexed file, the next record under the current index). If the FIND operation returns an error completion, the current-record context is undefined, and the next-record context is unchanged.

#### RETURNED VALUES

##### RRN

For a relative file or for a sequential disk file with fixed-length records, a sequential-access FIND operation returns the relative record number (RRN) for the found record in the 2-word BKT field of the RAB.

OPERATION MACRO DESCRIPTIONS  
\$FIND MACRO (SEQUENTIAL ACCESS)

RFA

The FIND operation returns the record file address (RFA) for the found record in the 3-word RFA field of the RAB.

Completion Status and Value

The FIND operation returns completion status in the 1-word STS field of the RAB and returns a completion value in the 1-word STV field of the RAB. Appendix A lists completion status symbols and values.

CHECKLISTS

Table 5-17 lists control block fields that are input to the FIND operation. Table 5-18 lists control block fields that are output by the FIND operation.

Table 5-17: FIND (Sequential Access) Input Fields

Block Field	Description
RAB ISI	Internal stream identifier
RAB RAC	Record access code
RB\$SEQ	Sequential access

Table 5-18: FIND (Sequential Access) Output Fields

Block Field	Description
RAB BKT	Relative record number (RRN)
RAB RFA	Record file address
RAB STS	Completion status code
RAB STV	Completion status value

## 5.10 \$FIND MACRO (KEY ACCESS)

The \$FIND macro calls the FIND operation routine to transfer a record (or part of a record) from a sequential disk file (with fixed-length records), a relative file, or an indexed file to an I/O buffer. The FIND operation transfers the entire record if the file is relative or indexed, or if it has blocked records; it may transfer only part of the record if the record spans block boundaries. The FIND operation does not transfer the record to a user buffer.

The target of a key-access FIND operation is the record having the specified key (under the specified match criterion). For a relative file or for a sequential disk file with fixed-length records, the key is a relative record number (RRN); for an indexed file, the key is an index key under the specified index.

### FORMAT

The format for the \$FIND is:

```
$FIND rabaddr[, [erraddr][, sucaddr]]
```

where rabaddr is the address of the RAB for the operation; erraddr is the address of the error handler for the operation; and sucaddr is the address of the success handler for the operation.

### CONTROL BLOCKS

You must supply a RAB for the FIND operation.

### OPTIONS

#### Internal Stream Identifier

The FIND operation reads the internal stream identifier from the 1-word ISI field of the RAB.

#### Key Access

Specify the RB\$KEY code in the 1-byte RAC field of the RAB.

#### Key of Reference (Indexed File)

Specify the key of reference in the 1-byte KRF field of the RAB. The key of reference is the reference number (REF field of KEY block) for the index you want to use for the FIND operation.

#### Key

Specify a buffer containing the key for the record to be found: specify the address of the key buffer in the 1-word KBF field of the RAB, and specify the size of the key in the 1-byte KSZ field of the RAB.

For a relative file, or for a sequential file with fixed-length records, specify a 4-byte binary relative record number (RRN) as the key, and specify the key size as 0 or 4.

## OPERATION MACRO DESCRIPTIONS

### \$FIND MACRO (KEY ACCESS)

For an indexed file, specify a key of the same type as the key for the current index, and specify a key size no greater than the key size for the current index. For a nonstring key, the specified key size must be the key size defined for the index (or, equivalently, 0); for a string key, if you specify a key size smaller than the key size for the index, the FIND operation searches for a record whose key begins with the specified partial key (under the specified key criterion).

#### Key Criterion

Specify a key-criterion mask in the 1-word ROP field of the RAB. The symbols for key-criterion masks are:

RB\$KGE Greater-than-or-equal key criterion  
RB\$KGT Greater-than key criterion

If you specify the key-greater criterion, the FIND operation searches for the first record whose key is greater than the key you specify; if you specify the key-greater-or-equal criterion, the FIND operation searches for the first record whose key is greater than or equal to the key you specify; if you specify neither criterion, the FIND operation searches for a record whose key exactly matches the key you specify. (It is illegal to specify both criteria.)

#### STREAM CONTEXT

The current-record context after a key access FIND operation is the found record; the next-record context is unchanged. If the FIND operation returns an error completion, the current-record context is undefined, and the next-record context is unchanged.

#### RETURNED VALUES

##### RFA

The FIND operation returns the record file address (RFA) for the found record in the 3-word RFA field of the RAB.

##### RRN

For a relative file or for a sequential disk file with fixed-length records, the FIND operation returns the RRN of the found record in the 2-word BKT field of the RAB.

#### Completion Status and Value

The FIND operation returns completion status in the 1-word STS field of the RAB and returns a completion value in the 1-word STV field of the RAB. Appendix A lists completion status symbols and values.

#### CHECKLISTS

Table 5-19 lists control block fields that are input to the FIND operation. Table 5-20 lists control block fields that are output by the FIND operation.

Table 5-19: FIND (Key Access) Input Fields

Block	Field	Description
RAB	ISI	Internal stream identifier
RAB	KBF	Key buffer address
RAB	KRF	Key of reference
RAB	KSZ	Key size (bytes)
RAB	RAC	Record access code
		RB\$KEY Key access
RAB	ROP	Record processing option mask
		RB\$KGE Greater-than-or-equal key criterion
		RB\$KGT Greater-than key criterion

Table 5-20: FIND (Key Access) Output Fields

Block	Field	Description
RAB	BKT	Relative record number (RRN)
RAB	RFA	Record file address
RAB	STS	Completion status code
RAB	STV	Completion status value

**OPERATION MACRO DESCRIPTIONS**  
**\$FIND MACRO (RFA ACCESS)**

**5.11 \$FIND MACRO (RFA ACCESS)**

The \$FIND macro calls the FIND operation routine to transfer a record (or part of a record) from a file to an I/O buffer. The FIND operation transfers the entire file if the file is relative or indexed, or if it has blocked records; it may transfer only part of the record if the record spans block boundaries. The FIND operation does not transfer the record to a user buffer.

The target of an RFA-access FIND operation is the record having the record file address (RFA) you specify.

**FORMAT**

The format for the \$FIND is:

```
$FIND rabaddr[, [erraddr] [, sucaddr]]
```

where rabaddr is the address of the RAB for the operation; erraddr is the address of the error handler for the operation; and sucaddr is the address of the success handler for the operation.

**CONTROL BLOCKS**

You must supply a RAB for the FIND operation.

**OPTIONS**

**Internal Stream Identifier**

The FIND operation reads the internal stream identifier from the 1-word ISI field of the RAB.

**RFA Access**

Specify the RB\$RFA code in the 1-byte RAC field of the RAB.

**RFA**

Specify the RFA for the record to be found in the 3-word RFA field of the RAB.

**STREAM CONTEXT**

The current-record context after an RFA access FIND operation is the found record (for an indexed file, in the context of the primary index); the next-record context is unchanged. If the FIND operation returns an error completion, the current-record context is undefined, and the next-record context is unchanged.

RETURNED VALUES

RRN

For a relative file or for a sequential disk file with fixed-length records, the FIND operation returns the RRN of the found record in the 2-word BKT field of the RAB.

Completion Status and Value

The FIND operation returns completion status in the 1-word STS field of the RAB and returns a completion value in the 1-word STV field of the RAB. Appendix A lists completion status symbols and values.

CHECKLISTS

Table 5-21 lists control block fields that are input to the FIND operation. Table 5-22 lists control block fields that are output by the FIND operation.

Table 5-21: FIND (RFA Access) Input Fields

Block Field	Description
RAB ISI	Internal stream identifier
RAB RAC	Record access code
	RB\$RFA RFA access
RAB RFA	Record file address

Table 5-22: FIND (RFA Access) Output Fields

Block Field	Description
RAB BKT	Relative record number (RRN)
RAB STS	Completion status code
RAB STV	Completion status value

**OPERATION MACRO DESCRIPTIONS**  
**\$FLUSH MACRO**

**5.12 \$FLUSH MACRO**

The \$FLUSH macro calls the FLUSH operation routine to write any unwritten buffers for a stream. The FLUSH operation does not affect stream context, except that the current-record context is undefined for a following TRUNCATE or UPDATE operation.

Note one special case: if a file was opened for deferred writing (FB\$DFW set in the FOP field of the FAB for the CREATE or OPEN operation), and was not opened for write sharing (FB\$WRI cleared in the SHR field of the FAB), then a buffer may be controlled by a different stream, and it will not be written by the FLUSH operation.

**FORMAT**

The format for the \$FLUSH is:

```
$FLUSH rabaddr[, [erraddr][, sucaddr]]
```

where rabaddr is the address of the RAB for the operation; erraddr is the address of the error handler for the operation; and sucaddr is the address of the success handler for the operation.

**CONTROL BLOCKS**

You must supply a RAB for the FLUSH operation.

**OPTIONS**

**Internal Stream Identifier**

The FLUSH operation reads the internal stream identifier from the 1-word ISI field of the RAB.

**STREAM CONTEXT**

The FLUSH operation does not affect stream context, except that the current-record context is undefined for a following TRUNCATE or UPDATE operation.

**RETURNED VALUES**

**Completion Status and Value**

The FLUSH operation returns completion status in the 1-word STS field of the RAB and returns a completion value in the 1-word STV field of the RAB. Appendix A lists completion status symbols and values.

**CHECKLISTS**

Table 5-23 lists control block fields that are input to the FLUSH operation. Table 5-24 lists control block fields that are output by the FLUSH operation.

Table 5-23: FLUSH Input Fields

Block Field	Description
RAB ISI	Internal stream identifier

Table 5-24: FLUSH Output Fields

Block Field	Description
RAB STS	Completion status code
RAB STV	Completion status value

**OPERATION MACRO DESCRIPTIONS**  
**\$FREE MACRO**

**5.13 \$FREE MACRO**

The \$FREE macro calls the FREE operation routine to free a locked bucket for a stream. The FREE operation does not affect stream context, except that the current-record context is undefined for a following DELETE, TRUNCATE, or UPDATE operation.

**FORMAT**

The format for the \$FREE is:

```
$FREE rabaddr[, [erraddr][, sucaddr]]
```

where rabaddr is the address of the RAB for the operation; erraddr is the address of the error handler for the operation; and sucaddr is the address of the success handler for the operation.

**CONTROL BLOCKS**

You must supply a RAB for the FREE operation.

**OPTIONS**

**Internal Stream Identifier**

The FREE operation reads the internal stream identifier from the 1-word ISI field of the RAB.

**STREAM CONTEXT**

The FREE operation does not affect stream context, except that the current-record context is undefined for a following DELETE, TRUNCATE, or UPDATE operation.

**RETURNED VALUES**

**Completion Status and Value**

The FREE operation returns completion status in the 1-word STS field of the RAB and returns a completion value in the 1-word STV field of the RAB. Appendix A lists completion status symbols and values.

**CHECKLISTS**

Table 5-25 lists control block fields that are input to the FREE operation. Table 5-26 lists control block fields that are output by the FREE operation.

Table 5-25: FREE Input Fields

Block	Field	Description
RAB	ISI	Internal stream identifier

Table 5-26: FREE Output Fields

Block	Field	Description
RAB	STS	Completion status code
RAB	STV	Completion status value

OPERATION MACRO DESCRIPTIONS  
\$GET MACRO (SEQUENTIAL ACCESS)

5.14 \$GET MACRO (SEQUENTIAL ACCESS)

The \$GET macro calls the GET operation routine to transfer a record from a file to an I/O buffer and to a user buffer.

The target of a sequential-access GET operation depends on whether the previous operation was a FIND operation:

- If the previous operation was a successful FIND operation, the target of a sequential-access GET operation is the current record (or the first following record if the current record was deleted or its key changed in the interim).
- If the previous operation was not a successful FIND operation, the target of a sequential-access GET operation is the next record (for an indexed file, the next record under the current index).

FORMAT

The format for the \$GET is:

```
$GET rabaddr[, [erraddr][, sucaddr]]
```

where rabaddr is the address of the RAB for the operation; erraddr is the address of the error handler for the operation; and sucaddr is the address of the success handler for the operation.

CONTROL BLOCKS

You must supply a RAB for the GET operation.

OPTIONS

Internal Stream Identifier

The GET operation reads the internal stream identifier from the 1-word ISI field of the RAB.

Sequential Access

Specify the RB\$SEQ code in the 1-byte RAC field of the RAB.

User Buffer

Specify a user buffer for the GET operation. The GET operation copies the retrieved record to this buffer if you do not specify locate mode (see next section, Locate Mode); the GET operation may copy the retrieved record to this buffer even if you specify locate mode.

Specify the address of the user buffer in the 1-word UBF field of the RAB, and specify the size (in bytes) of the user buffer in the 1-word USZ field of the RAB.

If the file is in VFC record format, specify the address of a buffer for the fixed-length portion of the record in the 1-word RHB field of the RAB.

### Locate Mode

If you want the GET operation to use locate mode (in which the record may not be transferred to the user buffer), set the RB\$LOC mask in the 1-word ROP field of the RAB; if you do not set this mask, the record is transferred to the user buffer.

### STREAM CONTEXT

The current-record context after a sequential access GET operation is the retrieved record; the next-record context is the record following the retrieved record.

If the GET operation returns an error completion, the current-record context is undefined, and the next-record context is unchanged.

### RETURNED VALUES

#### Record

The GET operation returns the address and size of the retrieved record in the 1-word RBF field of the RAB, and the size (in bytes) of the record in the 1-word RSZ field of the RAB.

If you did not specify locate mode for the GET operation, the record address returned in the RBF field is the address you specified in the UBF field; if you specified locate mode, the record address returned in the RBF field is either the address you specified in the UBF field, or the address of a location in an I/O buffer.

If the file is in VFC format, the GET operation writes the fixed-length portion of the record in the buffer you specified in the RHB field of the RAB.

#### RRN

For a relative file or for a sequential disk file with fixed-length records, a sequential-access GET operation returns the relative record number (RRN) for the retrieved record in the 2-word BKT field of the RAB.

#### RFA

The GET operation returns the record file address (RFA) for the retrieved record in the 3-word RFA field of the RAB.

#### Completion Status and Value

The GET operation returns completion status in the 1-word STS field of the RAB and returns a completion value in the 1-word STV field of the RAB. Appendix A lists completion status symbols and values.

### CHECKLISTS

Table 5-27 lists control block fields that are input to the GET operation. Table 5-28 lists control block fields that are output by the GET operation.

OPERATION MACRO DESCRIPTIONS  
 \$GET MACRO (SEQUENTIAL ACCESS)

Table 5-27: GET (Sequential Access) Input Fields

### 5.15 \$GET MACRO (KEY ACCESS)

The \$GET macro calls the GET operation routine to transfer a record from a sequential disk file (with fixed-length records), a relative file, or an indexed file to an I/O buffer and to a user buffer.

The target of a key-access GET operation is the record having the specified key (under the specified match criterion). For a relative file or for a sequential disk file with fixed-length records, the key is a relative record number (RRN); for an indexed file, the key is an index key under the specified index.

#### FORMAT

The format for the \$GET is:

```
$GET rabaddr[, [erraddr][, sucaddr]]
```

where rabaddr is the address of the RAB for the operation; erraddr is the address of the error handler for the operation; and sucaddr is the address of the success handler for the operation.

#### CONTROL BLOCKS

You must supply a RAB for the GET operation.

#### OPTIONS

##### Internal Stream Identifier

The GET operation reads the internal stream identifier from the 1-word ISI field of the RAB.

##### Key Access

Specify the RB\$KEY code in the 1-byte RAC field of the RAB.

##### Key of Reference (Indexed File)

Specify the key of reference in the 1-byte KRF field of the RAB. The key of reference is the reference number (REF field of KEY block) for the index you want to use for the GET operation.

##### Key

Specify a buffer containing the key for the record to be retrieved: specify the address of the key buffer in the 1-word KBF field of the RAB, and specify the size of the key in the 1-byte KSZ field of the RAB.

For a relative file or for a sequential file with fixed-length records, specify a 4-byte binary relative record number (RRN) as the key, and specify the key size as 0 or 4.

For an indexed file, specify a key of the same type as the key for the current index, and specify a key size no greater than the key size for the current index. For a nonstring key, the specified key size must be the key size defined for the index (or, equivalently, 0); for a

## OPERATION MACRO DESCRIPTIONS

### \$GET MACRO (KEY ACCESS)

string key, if you specify a key size smaller than the key size for the index, the GET operation searches for a record whose key begins with the specified partial key (under the specified key criterion).

#### Key Criterion

Specify a key-criterion mask in the 1-word ROP field of the RAB. The symbols for key-criterion masks are:

RB\$KGE Greater-than-or-equal key criterion  
RB\$KGT Greater-than key criterion

If you specify the key-greater criterion, the GET operation searches for the first record whose key is greater than the key you specify; if you specify the key-greater-or-equal criterion, the GET operation searches for the first record whose key is greater than or equal to the key you specify; if you specify neither criterion, the GET operation searches for a record whose key exactly matches the key you specify.

#### User Buffer

Specify a user buffer for the GET operation. The GET operation copies the retrieved record to this buffer if you do not specify locate mode (see next section, Locate Mode); the GET operation may copy the retrieved record to this buffer even if you specify locate mode.

Specify the address of the user buffer in the 1-word UBF field of the RAB, and specify the size (in bytes) of the user buffer in the 1-word USZ field of the RAB.

If the file is in VFC record format, specify the address of a buffer for the fixed-length portion of the record in the 1-word RHB field of the RAB.

#### Locate Mode

If you want the GET operation to use locate mode (in which the record may not be transferred to the user buffer), set the RB\$LOC mask in the 1-word ROP field of the RAB; if you do not set this mask, the record is transferred to the user buffer.

#### STREAM CONTEXT

The current-record context after a key access GET operation is the retrieved record; the next-record context is the record following the retrieved record.

If the GET operation returns an error completion, the current-record context is undefined, and the next-record context is unchanged.

#### RETURNED VALUES

##### Record

The GET operation returns the address and size of the retrieved record in the 1-word RBF field of the RAB, and the size (in bytes) of the record in the 1-word RSZ field of the RAB.

If you did not specify locate mode for the GET operation, the record address returned in the RBF field is the address you specified in the UBF field. If you specified locate mode, the record address returned in the RBF field is either the address you specified in the UBF field, or the address of a location in an I/O buffer.

If the file is in VFC format, the GET operation writes the fixed-length portion of the record in the buffer you specified in the RHB field of the RAB.

#### RRN

For a relative file or for a sequential disk file with fixed-length records, a key-access GET operation returns the relative record number (RRN) for the retrieved record in the 2-word BKT field of the RAB.

#### RFA

The GET operation returns the record file address (RFA) for the retrieved record in the 3-word RFA field of the RAB.

#### Completion Status and Value

The GET operation returns completion status in the 1-word STS field of the RAB and returns a completion value in the 1-word STV field of the RAB. Appendix A lists completion status symbols and values.

#### CHECKLISTS

Table 5-29 lists control block fields that are input to the GET operation. Table 5-30 lists control block fields that are output by the GET operation.

Table 5-29: GET (Key Access) Input Fields

Block Field	Description
RAB	ISI Internal stream identifier
RAB	KBF Key buffer address
RAB	KRF Key of reference
RAB	KSZ Key size (bytes)
RAB	RAC Record access code
	RB\$KEY Key access
RAB	RHB VFC control buffer address
RAB	ROP Record processing option mask
	RB\$KGE Greater-than-or-equal key criterion
	RB\$KGT Greater-than key criterion
	RB\$LOC Locate mode
RAB	UBF User buffer address
RAB	USZ User buffer size (bytes)

OPERATION MACRO DESCRIPTIONS  
\$GET MACRO (KEY ACCESS)

RAB	RSZ	Record size (bytes)
RAB	STS	Completion status code
RAB	STV	Completion status value

### 5.16 \$GET MACRO (RFA ACCESS)

The \$GET macro calls the GET operation routine to transfer a record from a file to an I/O buffer and to a user buffer.

The target of an RFA-access GET operation is the record having the record file address (RFA) you specify.

#### FORMAT

The format for the \$GET is:

```
$GET rabaddr[, [erraddr] [, sucaddr]]
```

where rabaddr is the address of the RAB for the operation; erraddr is the address of the error handler for the operation; and sucaddr is the address of the success handler for the operation.

#### CONTROL BLOCKS

You must supply a RAB for the GET operation.

#### OPTIONS

##### Internal Stream Identifier

The GET operation reads the internal stream identifier from the 1-word ISI field of the RAB.

##### RFA Access

Specify the RB\$RFA code in the 1-byte RAC field of the RAB.

##### RFA

Specify the RFA for the record to be retrieved in the 3-word RFA field of the RAB.

##### User Buffer

Specify a user buffer for the GET operation. The GET operation copies the retrieved record to this buffer if you do not specify locate mode (see next section, Locate Mode); the GET operation may copy the retrieved record to this buffer even if you specify locate mode.

Specify the address of the user buffer in the 1-word UBF field of the RAB, and specify the size (in bytes) of the user buffer in the 1-word USZ field of the RAB.

If the file is in VFC record format, specify the address of a buffer for the fixed-length portion of the record in the 1-word RHB field of the RAB.

**OPERATION MACRO DESCRIPTIONS**  
**\$GET MACRO (RFA ACCESS)**

**Locate Mode**

If you want the GET operation to use locate mode (in which the record may not be transferred to the user buffer), set the RB\$LOC mask in the 1-word ROP field of the RAB; if you do not set this mask, the record is transferred to the user buffer.

**STREAM CONTEXT**

The current-record context after an RFA access GET operation is the retrieved record (for an indexed file, in the context of the primary index); the next-record context is the record following the retrieved record. If the GET operation returns an error completion, the current-record context is undefined, and the next-record context is unchanged.

**RETURNED VALUES**

**Record**

The GET operation returns the address and size of the retrieved record in the 1-word RBF field of the RAB, and the size (in bytes) of the record in the 1-word RSZ field of the RAB.

If you did not specify locate mode for the GET operation, the record address returned in the RBF field is the address you specified in the UBF field. If you specified locate mode, the record address returned in the RBF field is either the address you specified in the UBF field, or the address of a location in an I/O buffer.

If the file is in VFC format, the GET operation writes the fixed-length portion of the record in the buffer you specified in the RHB field of the RAB.

**RRN**

For a relative file or for a sequential disk file with fixed-length records, an RFA-access GET operation returns the relative record number (RRN) for the retrieved record in the 2-word BKT field of the RAB.

**Completion Status and Value**

The GET operation returns completion status in the 1-word STS field of the RAB and returns a completion value in the 1-word STV field of the RAB. Appendix A lists completion status symbols and values.

**CHECKLISTS**

Table 5-31 lists control block fields that are input to the GET operation. Table 5-32 lists control block fields that are output by the GET operation.

Table 5-31: GET (RFA Access) Input Fields

Block Field	Description
RAB ISI	Internal stream identifier
RAB RAC	Record access code
	RB\$RFA RFA access
RAB RFA	Record file address
RAB RHB	VFC control buffer address
RAB ROP	Record processing option mask
	RB\$LOC Locate mode
RAB UBF	User buffer address
RAB USZ	User buffer size (bytes)

Table 5-32: GET (RFA Access) Output Fields

Block Field	Description
RAB BKT	Relative record number (RRN)
RAB RBF	Record buffer address
RAB RSZ	Record size (bytes)
RAB STS	Completion status code
RAB STV	Completion status value

OPERATION MACRO DESCRIPTIONS  
\$OPEN MACRO

5.17 \$OPEN MACRO

The \$OPEN macro calls the OPEN operation routine to open a file for processing by the calling task.

FORMAT

The format for the \$OPEN is:

```
$OPEN fabaddr[, [erraddr][, sucaddr]]
```

where fabaddr is the address of the FAB for the operation; erraddr is the address of the error handler for the operation; and sucaddr is the address of the success handler for the operation.

CONTROL BLOCKS

You must supply a FAB for the OPEN operation.

If you supply a NAM block and specify open by NAM block, the OPEN operation reads NAM block fields to obtain identifiers for the target file.

To supply a NAM block for the OPEN operation, specify the address of the NAM block in the 1-word NAM field of the FAB.

For each ALL block that you supply, the OPEN operation fills its fields with values describing the corresponding area (if any) of the file. You need not supply an ALL block for every area of the file. (If you are opening the file for block access, the OPEN operation writes information describing the file as a whole in the all block for area 0.)

For each KEY block that you supply, the OPEN operation fills its fields with values describing the corresponding index (if any) for the file. You need not supply a KEY block for every index of the file. (If you are opening the file for block access, the OPEN operation does not write in KEY blocks.)

If you supply a PRO block for a disk file, the OPEN operation fills its fields with values showing the owner and protection for the file.

If you supply a DAT block for a disk file, the OPEN operation fills its fields with values showing the creation date and revision date for the file.

If you supply a SUM block for a relative or indexed file, the OPEN operation fills its fields with values showing the number of areas and indexes for the file, and with its prologue version number. (If you are opening the file for block access, the OPEN operation returns the number of areas and number of keys as 0, and does not return the prologue version number.)

This information is especially useful if you do not know how many areas or keys an indexed file has when you open it. If you supply a SUM block for the OPEN operation, you can get the number of areas and number of indexes from its fields, and then supply the correct number of ALL blocks and KEY blocks for the DISPLAY operation.

To supply XABs (ALL, DAT, KEY, PRO, and SUM blocks) for the OPEN operation, specify the address of the first XAB in the 1-word XAB field of the FAB; specify the address of the next XAB (if any) in the 1-word NXT field of each XAB; specify 0 in the NXT field of the last XAB.

All KEY blocks must be together in the chain of XABs, and must be in ascending order (by the index reference number in the 1-byte REF field of the KEY block); the index reference numbers need not be consecutive.

All ALL blocks must be together in the chain of XABs, and must be in ascending order (by the area identifier in the 1-byte AID field of the ALL block); the area identifiers need not be consecutive.

Multiple DAT, PRO, or SUM XABs are illegal.

## OPTIONS

### File Specification (Nonwildcard OPEN Operation)

The OPEN operation constructs the full file specification from the file string, the default string (which contributes only elements not present in the file string), and RMS-11 defaults (which contribute elements not present in either the file string or the default string).

RMS-11 defaults are:

- Device -- The device to which the specified logical channel is assigned, or SY: if the specified logical channel is not assigned to any device.
- Directory -- The current directory for the task.
- Name, type, -- Defaulted to null.

The file string and the default string must not contain wildcards.

Specify the address of the file string in the 1-word FNA field of the FAB. Specify the size (in bytes) of the file string in the 1-byte FNS field of the FAB; if you specify 0 in the FNS field, the OPEN operation uses no file string.

Specify the address of the default string in the 1-word DNA field of the FAB. Specify the size (in bytes) of the default string in the 1-byte DNS field of the FAB; if you specify 0 in the DNS field, the OPEN operation uses no default string.

If you set the FB\$FID mask in the 1-word FOP field of the FAB and supply a NAM block, the OPEN operation reads the device identifier from the 2-word DVI field of the NAM block; if this value is nonzero, the specified device overrides the device in the merged string.

In the same circumstance, the OPEN operation reads the file identifier from the 3-word FID field of the NAM block; if this value is zero, the specified file overrides any directory, name, and type elements previously obtained.

**OPERATION MACRO DESCRIPTIONS**  
**\$OPEN MACRO**

**Open with Wildcard Context**

If you want to open a file that was found by a wildcard SEARCH operation (using the FAB and NAM block that the SEARCH operation used), set the FB\$FID mask in the 1-word FOP field of the FAB; this causes the OPEN operation to open the file without altering wildcard context.

**Expanded String Buffer**

If you want the OPEN operation to return the expanded string for the opened file, provide a buffer for the string. Specify the address of the expanded string buffer in the 1-word ESA field of the NAM block and its size (in bytes) in the 1-byte ESS field of the NAM block; if you specify 0 in the ESS field, the OPEN operation does not return the expanded string.

**Key Name Buffer**

If you want the key name string for an index returned to a buffer, supply a KEY block for the index. Specify the index reference number in the 1-byte REF field of the KEY block, and specify the address of a 32-byte buffer in the 1-word KNM field of the KEY block. If you do not supply a KEY block for an index, or if you specify 0 in its KNM field, the OPEN operation does not return the key name string.

**While-Open Default Extension Sizes**

If you want to override the default extension size for the file while it is open, specify the while-open default file extension size (in blocks) in the 1-word DEQ field of the FAB. If you specify 0, the OPEN operation does not establish a while-open default extension size for the file; instead, it uses the permanent default extension size.

The while-open default extension size for a file remains in force while the file is open, but does not change the file extension size established when the file was created.

**Private Buffer Pool**

If you want the OPEN operation to use a private buffer pool instead of the central buffer pool, specify the address of the (word-aligned) private buffer pool in the 1-word BPA field of the FAB, and its size (in bytes) in the 1-word BPS field of the FAB; this size must be a multiple of 4.

If you specify 0 in either the BPA field or the BPS field, the OPEN operation uses the central buffer pool.

The pool that the OPEN operation uses is also used by the DISPLAY and EXTEND operations, and by stream and record or block operations while the file is open.

**Logical Channel**

Specify the logical channel for the OPEN operation in the 1-byte LCH field of the FAB. The logical channel number must not be the same as the logical channel number for any already-open file, and must not be 0.

The logical channel that the OPEN operation uses is also used by the DISPLAY and EXTEND operations, and by stream and record or block operations while the file is open.

### Requested-Access

Specify one or more requested-access masks in the 1-byte FAC field of the FAB. This mask determines the access that the opening program has while the file is open. If you specify no requested-access mask, find/get access is allowed (the OPEN operation uses the mask FB\$GET). The symbols for requested-access masks are:

```

FB$DEL  Request find/get/delete access
FB$GET  Request find/get access
FB$PUT  Request put access
FB$REA  Request block read access
FB$TRN  Request find/get/truncate access
FB$UPD  Request find/get/update access
FB$WRT  Request block write access

```

Note that FB\$REA and FB\$WRT override any record access requested.

### Access Sharing

Specify the kinds of access that your program will share with other programs by setting an access-sharing mask in the 1-byte SHR field of the FAB. The symbols for access-sharing masks are:

```

FB$GET  Share find/get access
FB$NIL  No access sharing
FB$WRI  Share find/get/put/update/delete access

```

The kinds of access sharing are:

- **Shared read access**

Your program is willing to allow other programs to read the file, but not to write it.

Even if your program specifies shared read access, other programs will be unable to read (or write) the file if your program requests any form of write access.

- **Shared write access**

Your program is willing to allow other programs to both read and write the file. Shared write access is not allowed for a sequential file unless the file has undefined record format and your program opens the file for block access; shared write access is also not allowed for a relative or indexed file that your program opens for block access. In such cases, RMS-11 automatically converts the shared write access specification to a shared read access specification internally.

- **No shared access**

Your program is not willing to allow other programs to either read or write the file. RMS-11 does, however, allow other programs to read the file unless your program also requests some form of write access.

**OPERATION MACRO DESCRIPTIONS**  
**\$OPEN MACRO**

**Deferred Writing**

If you want deferred buffer writing for the open file, set the FB\$DFW mask in the 1-word FOP field of the FAB; This means that RMS-11 does not necessarily write its buffers during a write-type operation (DELETE, PUT, or UPDATE), but instead writes buffers only when it needs them for other operations (or when your program executes the FLUSH operation for the stream).

If you do not set the FB\$DFW mask, the DELETE, PUT, and UPDATE operations write buffers to the file immediately.

Note that record operations always use a form of deferred buffer writing for sequential files, and that block operations never use deferred buffer writing. Therefore you need only decide whether to use deferred writing for a record stream to a relative or indexed file.

**Magtape Beginning-of-File Positioning**

If you have requested some form of write access, and if you want a magtape file positioned to the beginning of the file when it is opened, set the FB\$NEF mask in the 1-word FOP field of the FAB; if you do not set this mask, and if you requested some form of write access, the magtape is positioned to the end-of-file when the file is opened.

**Rewinding Magtape Before Open**

If you want a magtape rewound before a magtape file is opened, set the FB\$RWO mask in the 1-word FOP field of the FAB; if you do not set this mask, the OPEN operation searches only from the current magtape position to the end of the magtape.

**Rewinding Magtape on Close**

If you want the magtape rewound when the opened file is closed, set the FB\$RWC mask in the 1-word FOP field of the FAB. If you do not set this mask, the magtape will not be rewound on close unless you set the FB\$RWC mask for the CLOSE operation. Note, however, that if you set the FB\$RWC mask for the OPEN operation, the magtape will be rewound even if you do not set the FB\$RWC mask for the CLOSE operation.

**RETURNED VALUES**

**Internal File Identifier**

The OPEN operation writes an internal file identifier in the 1-word IFI field of the FAB. (The CLOSE operation clears the internal file identifier.)

The CLOSE, CONNECT, DISPLAY, and EXTEND operations read the internal file identifier; do not alter the IFI field while the file is open.

### Device Characteristics

The OPEN operation returns device characteristics as masks in the 1-byte DEV field of the FAB. The device characteristics are:

- Printer or terminal (indicated by the set FB\$CCL mask in the 1-byte DEV field of the FAB and the set FB\$REC mask in the 1-byte DEV field of the FAB; for a terminal, the FB\$TRM mask in the 1-byte DEV field of the FAB is also set); RMS-11 treats a printer or terminal as a unit-record device.
- Disk, DECTape, or DECTAPE II (indicated by the set FB\$MDI mask in the 1-byte DEV field of the FAB); RMS-11 treats a disk, DECTape, or DECTAPE II as a disk device.
- Unit-record device (indicated by the set FB\$REC mask in the 1-byte DEV field of the FAB).
- Non-ANSI magtape or cassette tape (indicated by the set FB\$SDI mask in the 1-byte DEV field of the FAB and the set FB\$REC mask in the 1-byte DEV field of the FAB); RMS-11 treats a non-ANSI magtape or a cassette tape as a unit-record device.
- ANSI-format magtape (indicated by the set FB\$SQD mask in the 1-byte DEV field of the FAB).

### Device and File Identifiers

If you supply a NAM block, the OPEN operation writes a device identifier in the 2-word DVI field of the NAM block and a file identifier in the 3-word FID field of the NAM block.

### Expanded String

If you specify a buffer for the expanded string for the file (ESA and ESS fields in the NAM block), the OPEN operation writes the expanded string for the opened file in this buffer, and writes the length (in bytes) of the string in the 1-byte ESL field of the NAM block.

### File Allocation, Bucket Size, and Contiguity

The OPEN operation writes the file allocation size (in blocks) in the 2-word ALQ field of the FAB, and the file bucket size or largest area bucket size (in blocks) in the 1-byte BKS field of the FAB. If the file is contiguous, the OPEN operation sets the FB\$CTG mask in the 1-word FOP field of the FAB.

### Extension size

The OPEN operation writes the current default extension size for the open file in the 1-word DEQ field of the FAB.

### File Organization

The OPEN operation writes the file organization code in the 1-byte ORG field of the FAB. The symbols for file organization codes are:

FB\$IDX Indexed file organization  
FB\$REL Relative file organization  
FB\$SEQ Sequential file organization

**OPERATION MACRO DESCRIPTIONS**  
**\$OPEN MACRO**

**Record Format**

The OPEN operation writes the record format code in the 1-byte RFM field of the FAB. The symbols for record format codes are:

FB\$FIX Fixed-length record format  
FB\$STM Stream record format  
FB\$UDF Undefined record format  
FB\$VAR Variable-length record format  
FB\$VFC VFC record format

If the record format is VFC, the OPEN operation writes the size (in bytes) of the VFC header field in the 1-byte FSZ field of the FAB; otherwise it writes 0 in the FSZ field.

**Blocked Records (Sequential Disk File)**

If the file was created specifying blocked records, the OPEN operation sets the FB\$BLK mask in the 1-byte RAT field of the FAB. (The OPEN operation sets the mask if it was set when the file was created, even if the file is not a sequential file; preservation of this mask allows you to copy a sequential file to a file of a different organization and back without losing the blocked-record characteristic.)

**Record-Output Handling**

The OPEN operation writes the record-output mask in the 1-byte RAT field of the FAB. The symbols for record-output masks are:

FB\$CR Add CRLF to print record (LF-record-CR)  
FB\$FTN FORTRAN-style carriage-control character in record  
FB\$PRN VFC print record handling

**Record Size**

The OPEN operation writes the maximum permitted record size (in bytes) in the 1-word MRS field of the FAB.

**Maximum Record Number**

If the file is a relative file (FB\$REL in the ORG field), the OPEN operation writes the maximum record number in the 2-word MRN field of the FAB (unless you are opening the file for block access).

**Cluster Size**

The OPEN operation writes the cluster size (in blocks) for the file in the 1-byte RTV field of the FAB. A byte value of -1 implies a cluster size of 256 blocks.

**Magtape Block Size**

For a magtape file, the OPEN operation writes the block size (in characters) in the 1-word BLS field of the FAB.

### Longest Record Length

The OPEN operation writes the length of the longest record in the file in the 1-word LRL field of the FAB; this value is meaningful only for sequential files.

### Area Descriptions

For each ALL block that you supply, the OPEN operation writes a description in its fields of the corresponding area of the file (unless you are opening the file for block access). Area 0 is described in the ALL block containing 0 in its AID field, area 1 is described in the ALL block containing 1 in its AID field, and so forth.

The OPEN operation writes three sizes for a file area: the size (in blocks) of the unused portion of the area in the 2-word ALQ field of the ALL block, the default area extension size (in blocks) in the 1-word DEQ field of the ALL block, and the area bucket size (in blocks) in the 1-byte BKZ field of the ALL block. (If you are opening the file for block access, only the ALL block for area 0 is written, and the ALL block contains the current file allocation size, default file extension size, and file bucket size.)

The OPEN operation clears the 1-byte ALN field of the ALL block. If you are opening a sequential or relative file for any access, or an indexed file for block access, the OPEN operation sets the XB\$CTG mask in the 1-byte AOP field of the ALL block if the file is contiguous; otherwise it clears the entire 1-byte AOP field of the ALL block.

### Key Descriptions

For each KEY block that you supply, the OPEN operation writes a description in its fields of the corresponding index of the file. (The OPEN operation does not write in KEY blocks if you are opening the file for block access.)

The primary index is described in the KEY block containing 0 in its REF field, the first alternate index is described in the KEY block containing 1 in its REF field, and so forth.

The OPEN operation writes the key data type code in the 1-byte DTP field of the KEY block. The symbols for key data type codes are:

XB\$BN2	16-bit unsigned integer
XB\$BN4	32-bit unsigned integer
XB\$IN2	15-bit signed integer
XB\$IN4	31-bit signed integer
XB\$PAC	Packed decimal number
XB\$STG	String

The OPEN operation writes the sizes of key segments in the 8-byte SIZ field of the KEY block. The size (in bytes) of the first key segment is in the first byte of the SIZ field, the size of the second segment is in the second byte of the SIZ field, and so forth. If the key has fewer than eight segments, the first byte containing 0 establishes the number of key segments.

**OPERATION MACRO DESCRIPTIONS**  
**\$OPEN MACRO**

The OPEN operation writes the positions of key segments in the 8-word POS field of the KEY block. The position (leftmost position is 0) of the first key segment is in the first word of the POS field, the position of the second segment is in the second word of the POS field, and so forth. If the key has fewer than eight segments, the remaining words of the POS field contain unpredictable values.

The OPEN operation writes a key flags mask in the 1-byte FLG field of the KEY block. The symbols for key flags masks are:

XB\$CHG Record key changes allowed on update  
XB\$DUP Duplicate record keys allowed  
XB\$INI No entries yet made in index  
XB\$NUL Null record keys not indexed

The OPEN operation writes the null-key character in the 1-byte NUL field of the KEY block; this character is meaningful only if the XB\$NUL mask in the FLG field is set and if the key is a string key (XB\$STG in the DTP field).

The OPEN operation writes area numbers for the index: the area for the data level in the 1-byte DAN field of the KEY block, the area for the lowest index level in the 1-byte LAN field of the KEY block, and the area for higher index levels in the 1-byte IAN field of the KEY block.

The OPEN operation writes bucket fill numbers for the index areas: the fill number for the data area in the 1-word DFL field of the KEY block, and the fill number for the index areas in the 1-word IFL field of the KEY block.

The OPEN operation writes bucket sizes for index areas: the data area bucket size (in blocks) in the 1-byte DBS field of the KEY block, and the index area bucket size (in blocks) in the 1-byte IBS field of the KEY block.

The OPEN operation writes virtual block numbers for the index areas: the virtual block number for the first data bucket in the 2-word DVB field of the KEY block, and the virtual block number of the root index bucket in the 2-word RVB field of the KEY block.

The OPEN operation writes the number of levels in the index (not including the data level) in the 1-byte LVL field of the KEY block.

The OPEN operation writes the minimum size (in bytes) of a record that contains the key for the index in the 1-word MRL field of the KEY block.

The OPEN operation writes key segment information for the index: the number of key segments in the 1-byte NSG field of the KEY block, and the total key size (sum of segments, in bytes) in the 1-byte TKS field of the KEY block.

**File Owner and Protection (Disk File)**

If the file is a disk file, and if you supply a PRO block, the OPEN operation writes the project (or group) portion of the file owner code in the 1-word PRJ field of the PRO block, the programmer (or member) portion of the file owner code in the 1-word PRG field of the PRO block, and the file protection code in the 1-word PRO field of the PRO block.

### File Dates

If you supply a DAT block for a disk file, the OPEN operation writes two values in its fields: the creation date in the 4-word CDT field of the DAT block and the revision date in the 4-word RDT field of the DAT block.

The revision date has two possible meanings, depending upon the DSKINT option specified by the system manager: 1) the date the file was last opened or 2) the date the file was last accessed for writing.

### File Summary Information

If you supply a SUM block and are opening an indexed file, the OPEN operation writes three values in its fields: the number of file areas in the 1-byte NOA field of the SUM block, the number of file indexes in the 1-byte NOK field of the SUM block, and the prologue version number (for a relative or indexed file) in the 1-word PVN field of the SUM block. (If you are opening the file for block access, the OPEN operation returns the number of areas and the number of keys as 0, and does not return the prologue version number.)

### File Specification Characteristics

The OPEN operation sets masks in the 1-word FNB field of the NAM block to show which file specification elements were present in the file string and default string. These masks and their meanings are:

NB\$NOD	Node in file string or default string
NB\$DEV	Device in file string or default string
NB\$DIR	Directory in file string or default string
NB\$QUO	Quoted string in file string or default string
NB\$NAM	File name in file string or default string
NB\$TYP	File type in file string or default string
NB\$VER	File version in file string or default string
NB\$WDI	Wildcard directory in file string or default string
NB\$WNA	Wildcard file name in file string or default string
NB\$WTY	Wildcard file type in file string or default string
NB\$WVE	Wildcard file version in file string or default string

### Wildcard Context Information

If you cleared the FB\$FID mask, the OPEN operation clears the NB\$WCH mask in the 1-word FNB field of the NAM block and the 1-byte RSL field of the NAM block; this shows that no wildcard context information exists after the operation and that no resultant string was returned. If you set the FB\$FID mask, the OPEN operation does not alter the NB\$WCH mask, and (if the NB\$WCH mask is set) does not alter the RSL field.

### Completion Status and Value

The OPEN operation returns completion status in the 1-word STS field of the FAB and returns a completion value in the 1-word STV field of the FAB. Appendix A lists completion status symbols and values.

OPERATION MACRO DESCRIPTIONS  
 \$OPEN MACRO

CHECKLISTS

Table 5-33 lists control block fields that are input to the OPEN operation. Table 5-34 lists control block fields that are output by the OPEN operation.

Table 5-33: OPEN Input Fields

Block	Field	Description
ALL	AID	Area number
ALL	NXT	Next XAB address
DAT	NXT	Next XAB address
FAB	BPA	Private buffer pool address
FAB	BPS	Private buffer pool size (bytes)
FAB	DEQ	While-open file default extension size (blocks)
FAB	DNA	Default string address
FAB	DNS	Default string size (bytes)
FAB	FAC	Requested access mask
	FB\$DEL	Request find/get/delete access
	FB\$GET	Request find/get access
	FB\$PUT	Request put access
	FB\$REA	Request block read access
	FB\$TRN	Request find/get/truncate access
	FB\$UPD	Request find/get/update access
	FB\$WRT	Request block write access
FAB	FNA	File string address
FAB	FNS	File string size (bytes)
FAB	FOP	File processing option mask
	FB\$DFW	Defer writing
	FB\$FID	Use information in NAM block
	FB\$RWC	Rewind magtape after closing file
	FB\$RWO	Rewind magtape before searching for file
FAB	LCH	Logical channel number
FAB	NAM	NAM block address
FAB	SHR	Shared access mask
	FB\$GET	Share find/get access
	FB\$NIL	No access sharing
	FB\$WRI	Share find/get/put/update/delete access
FAB	XAB	XAB address
KEY	KNM	Key name buffer address
KEY	NXT	Next XAB address
KEY	REF	Index reference number
NAM	DVI	Device identifier
NAM	ESA	Expanded string buffer address
NAM	ESS	Expanded string buffer size (bytes)
NAM	FID	File identifier
NAM	FNB	File specification mask
	NB\$WCH	Wildcard context established
PRO	NXT	Next XAB address
SUM	NXT	Next XAB address

Table 5-34: OPEN Output Fields

Block	Field	Description
ALL	ALN	Area alignment mask
ALL	ALQ	Unused area allocation size (blocks)
ALL	AOP	Area option mask
		XB\$CTG Contiguous area
		XB\$HRD Hard area location (cleared)
ALL	BKZ	Area bucket size (blocks)
ALL	DEQ	Area default extension size (blocks)
DAT	CDT	File creation date
DAT	RDT	File revision date
FAB	ALQ	Current file allocation (blocks)
FAB	BKS	File bucket size (blocks)
FAB	BLS	Magtape block size (characters)
FAB	DEQ	Current file default extension size (blocks)
FAB	DEV	Device characteristic mask
		FB\$CCL Carriage-control device
		FB\$MDI Multidirectory device
		FB\$REC Record-oriented device
		FB\$SDI Single-directory device
		FB\$SQD Sequential device
		FB\$TRM Terminal device
FAB	FOP	File processing option mask
		FB\$CTG Contiguous file
FAB	FSZ	Fixed control area size for VFC records (bytes)
FAB	IFI	Internal file identifier
FAB	LRL	Longest record length
FAB	MRN	Maximum record number
FAB	MRS	Maximum record size (bytes)
FAB	ORG	File organization code
		FB\$SEQ Sequential file organization
		FB\$REL Relative file organization
		FB\$IDX Indexed file organization
FAB	RAT	Record handling mask
		FB\$BLK Blocked records
		FB\$CR Add CRLF to print record (LF-record-CR)
		FB\$FTN FORTRAN-style carriage-control character in record
		FB\$PRN VFC print record handling
FAB	RFM	Record format code
		FB\$UDF Undefined record format
		FB\$FIX Fixed-length record format
		FB\$VAR Variable-length record format
		FB\$VFC VFC record format
		FB\$STM Stream record format

Table 5-34 (Cont.): OPEN Output Fields

Block	Field	Description
FAB	RTV	Cluster size (blocks)
FAB	STS	Completion status code
FAB	STV	Completion status value
KEY	DAN	Data area number
KEY	DBS	Data area bucket size (blocks)
KEY	DFL	Data bucket fill factor
KEY	DTP	Key data type code
		XB\$BN2 16-bit unsigned integer
		XB\$BN4 32-bit unsigned integer
		XB\$IN2 15-bit signed integer
		XB\$IN4 31-bit signed integer
		XB\$PAC Packed decimal number
		XB\$STG String
KEY	DVB	First data bucket virtual block number
KEY	FLG	Index option mask
		XB\$CHG Record key changes allowed on update
		XB\$DUP Duplicate record keys allowed
		XB\$INI No entries yet made in index
		XB\$NUL Null record keys not indexed
KEY	IAN	Higher level index area number
KEY	IBS	Index area bucket size (blocks)
KEY	IFL	Index bucket fill factor
KEY	LAN	Lowest index level area number
KEY	LVL	Number of index levels (not including data level)
KEY	MRL	Minimum length of record containing key (bytes)
KEY	NSG	Key segment count
KEY	NUL	Null key character
KEY	POS	Key segment positions
KEY	RVB	Root index bucket virtual block number
KEY	SIZ	Key segment sizes (bytes)
KEY	TKS	Total key size (sum of key segment sizes) (bytes)
NAM	DVI	Device identifier
NAM	ESL	Expanded string length (bytes)
NAM	FID	File identifier
NAM	FNB	File specification mask
		NB\$NOD Node in file string or default string
		NB\$DEV Device in file string or default string
		NB\$DIR Directory in file string or default string
		NB\$QUO Quoted string in file string or default string
		NB\$NAM File name in file string or default string
		NB\$TYP File type in file string or default string
		NB\$VER File version in file string or default string
		NB\$WDI Wildcard directory in file string or default string
		NB\$WNA Wildcard file name in file string or default string
		NB\$WTY Wildcard file type in file string or default string
		NB\$WVE Wildcard file version in file string or default string
		NB\$WCH Wildcard context established

(Continued on next page)

Table 5-34 (Cont.): OPEN Output Fields

Block	Field	Description
NAM	RSL	Resultant string length (bytes) (cleared)
PRO	PRG	Programmer or member portion of file owner code
PRO	PRJ	Project or group portion of file owner code
PRO	PRO	File protection code
SUM	NOA	Number of areas
SUM	NOK	Number of indexes
SUM	PVN	Prologue version number

**OPERATION MACRO DESCRIPTIONS**  
**\$PARSE MACRO**

**5.18 \$PARSE MACRO**

The \$PARSE macro calls the PARSE operation routine to analyze a file specification.

**FORMAT**

The format for the \$PARSE is:

```
$PARSE fabaddr[, [erraddr][, sucaddr]]
```

where fabaddr is the address of the FAB for the operation; erraddr is the address of the error handler for the operation; and sucaddr is the address of the success handler for the operation.

**CONTROL BLOCKS**

You must supply a FAB for the PARSE operation.

If you supply a NAM block for the PARSE operation, the operation routine writes file information in its fields. This information is suitable as input to subsequent wildcard SEARCH operations.

To supply a NAM block for the PARSE operation, specify the address of the NAM block in the 1-word NAM field of the FAB.

To supply XABs (ALL, DAT, KEY, PRO, and SUM blocks) for the PARSE operation, specify the address of the first XAB in the 1-word XAB field of the FAB; specify the address of the next XAB (if any) in the 1-word NXT field of each XAB; specify 0 in the NXT field of the last XAB.

All KEY blocks must be together in the chain of XABs, and must be in ascending order (by the index reference number in the 1-byte REF field of the KEY block); the index reference numbers need not be consecutive.

All ALL blocks must be together in the chain of XABs, and must be in ascending order (by the area identifier in the 1-byte AID field of the ALL block); the area identifiers need not be consecutive.

Multiple DAT, PRO, or SUM XABs are illegal.

**OPTIONS**

**File Specification**

The PARSE operation constructs the full file specification from the file string, the default string (which contributes only elements not present in the file string), and RMS-11 defaults (which contribute elements not present in either the file string or the default string).

RMS-11 defaults are:

- Device -- The device to which the specified logical channel is assigned, or SY: if the specified logical channel is not assigned to any device.
- Directory -- The current directory for the task.
- Name, type, -- Defaulted to null.

Specify the address of the file string in the 1-word FNA field of the FAB. Specify the size (in bytes) of the file string in the 1-byte FNS field of the FAB; if you specify 0 in the FNS field, the PARSE operation uses no file string.

Specify the address of the default string in the 1-word DNA field of the FAB. Specify the size (in bytes) of the default string in the 1-byte DNS field of the FAB; if you specify 0 in the DNS field, the PARSE operation uses no default string.

#### Expanded String Buffer

If you want the PARSE operation to return the expanded string for the file, provide a buffer for the string. If you want subsequent wildcard SEARCH operations to use the results of the PARSE operation, you must provide an expanded string buffer.

Specify the address of the expanded string buffer in the 1-word ESA field of the NAM block. Specify the size (in bytes) of the expanded string buffer in the 1-byte ESS field of the NAM block; if you specify 0 in the ESS field, the PARSE operation does not return the expanded string.

#### Private Buffer Pool

If you want the PARSE operation to use a private buffer pool instead of the central buffer pool, specify the address of the (word-aligned) private buffer pool in the 1-word BPA field of the FAB, and its size (in bytes) in the 1-word BPS field of the FAB; this size must be a multiple of 4.

If you specify 0 in either the BPA field or the BPS field, the PARSE operation uses the central buffer pool.

#### Logical Channel

Specify the logical channel for the PARSE operation in the 1-byte LCH field of the FAB. The logical channel number must not be the same as the logical channel number for any already-open file, and must not be 0.

#### RETURNED VALUES

#### Wildcard Initialization

If you supplied a NAM block to be initialized for wildcard SEARCH operations, the PARSE operation clears several fields: the 1-byte RSL field of the NAM block, the 1-word WCC field of the NAM block, and the 1-word WDI field of the NAM block. These cleared fields are part of the initialization for subsequent SEARCH operations.

## OPERATION MACRO DESCRIPTIONS

### \$PARSE MACRO

The PARSE operation writes a match-pattern (for subsequent wildcard SEARCH operations) in the expanded string buffer, and writes the length (in bytes) of the expanded string in the 1-byte ESL field of the NAM block.

The PARSE operation sets the NB\$WCH mask in the 1-word FNB field of the NAM block, showing that wildcard information in the NAM block is initialized.

### Device Characteristics

The PARSE operation returns device characteristics as masks in the 1-byte DEV field of the FAB. The device characteristics are:

- Printer or terminal (indicated by the set FB\$CCL mask in the 1-byte DEV field of the FAB and the set FB\$REC mask in the 1-byte DEV field of the FAB; for a terminal, the FB\$TRM mask in the 1-byte DEV field of the FAB is also set); RMS-11 treats a printer or terminal as a unit-record device.
- Disk, DECTape, or DECTAPE II (indicated by the set FB\$MDI mask in the 1-byte DEV field of the FAB); RMS-11 treats a disk, DECTape, or DECTAPE II as a disk device.
- Unit-record device (indicated by the set FB\$REC mask in the 1-byte DEV field of the FAB).
- Non-ANSI magtape or cassette tape (indicated by the set FB\$SDI mask in the 1-byte DEV field of the FAB and the set FB\$REC mask in the 1-byte DEV field of the FAB); RMS-11 treats a non-ANSI magtape or a cassette tape as a unit-record device.
- ANSI-format magtape (indicated by the set FB\$SQD mask in the 1-byte DEV field of the FAB).

### Device Identifier

If you supply a NAM block, the PARSE operation writes a device identifier in the 2-word DVI field of the NAM block.

### File Specification Characteristics

The PARSE operation sets masks in the 1-word FNB field of the NAM block to show which file specification elements were present in the file string and default string. These masks and their meanings are:

NB\$NOD	Node in file string or default string
NB\$DEV	Device in file string or default string
NB\$DIR	Directory in file string or default string
NB\$QUO	Quoted string in file string or default string
NB\$NAM	File name in file string or default string
NB\$TYP	File type in file string or default string
NB\$VER	File version in file string or default string
NB\$WDI	Wildcard directory in file string or default string
NB\$WNA	Wildcard file name in file string or default string
NB\$WTY	Wildcard file type in file string or default string
NB\$WVE	Wildcard file version in file string or default string

### Expanded String

If you supply a NAM block, and if the input file specification string does not contain wildcard characters, the PARSE operation writes the expanded string in the expanded string buffer; this string is a fully qualified file specification except that the file version number (if any) from the input file specification is unchanged.

### Completion Status and Value

The PARSE operation returns completion status in the 1-word STS field of the FAB and returns a completion value in the 1-word STV field of the FAB. Appendix A lists completion status symbols and values.

### CHECKLISTS

Table 5-35 lists control block fields that are input to the PARSE operation. Table 5-36 lists control block fields that are output by the PARSE operation.

**Table 5-35: PARSE Input Fields**

Block Field	Description
ALL NXT	Next XAB address
DAT NXT	Next XAB address
FAB BPA	Private buffer pool address
FAB BPS	Private buffer pool size (bytes)
FAB DNA	Default string address
FAB DNS	Default string size (bytes)
FAB FNA	File string address
FAB FNS	File string size (bytes)
FAB LCH	Logical channel number
FAB NAM	NAM block address
KEY NXT	Next XAB address
NAM ESA	Expanded string buffer address
NAM ESS	Expanded string buffer size (bytes)
PRO NXT	Next XAB address
SUM NXT	Next XAB address

**Table 5-36: PARSE Output Fields**

Block Field	Description
FAB DEV	Device characteristic mask
	FB\$CCL Carriage-control device
	FB\$MDI Multidirectory device
	FB\$REC Record-oriented device
	FB\$SDI Single-directory device
	FB\$SQD Sequential device
	FB\$TRM Terminal device
FAB STS	Completion status code
FAB STV	Completion status value
NAM DVI	Device identifier
NAM ESL	Expanded string length (bytes)

(Continued on next page)

Table 5-36 (Cont.): PARSE Output Fields

Block	Field	Description
NAM	FNB	File specification mask
	NB\$NOD	Node in file string or default string
	NB\$DEV	Device in file string or default string
	NB\$DIR	Directory in file string or default string
	NB\$QUO	Quoted string in file string or default string
	NB\$NAM	File name in file string or default string
	NB\$TYP	File type in file string or default string
	NB\$VER	File version in file string or default string
	NB\$WCH	Wildcard context established
	NB\$WDI	Wildcard directory in file string or default string
	NB\$WNA	Wildcard file name in file string or default string
	NB\$WTY	Wildcard file type in file string or default string
	NB\$WVE	Wildcard file version in file string or default string
NAM	RSL	Resultant string length (bytes) (cleared)
NAM	WCC	Wildcard context (cleared)
NAM	WDI	Wildcard directory context (cleared)

### 5.19 \$PUT MACRO (SEQUENTIAL ACCESS)

The \$PUT macro calls the PUT operation routine to transfer a record from a user buffer to an I/O buffer and to a file.

The target of a sequential-access PUT operation depends on the file organization:

- For a sequential file, the target of a sequential-access PUT operation is the end-of-file, and the next-record context must be the end-of-file.
- For a relative file, the target of a sequential-access PUT operation is the next cell (as determined by the next-record context or by the context of an immediately preceding sequential access PUT operation).
- For an indexed file, a sequential-access PUT operation has no target; the PUT operation inserts the record and updates indexes. If the immediately preceding operation was also a sequential access PUT operation, the primary key value in your record must be greater than or equal to the primary key value of the preceding record.

#### FORMAT

The format for the \$PUT is:

```
$PUT rabaddr[, [erraddr] [, sucaddr]]
```

where rabaddr is the address of the RAB for the operation; erraddr is the address of the error handler for the operation; and sucaddr is the address of the success handler for the operation.

#### CONTROL BLOCKS

You must supply a RAB for the PUT operation.

#### OPTIONS

##### Internal Stream Identifier

The PUT operation reads the internal stream identifier from the 1-word ISI field of the RAB.

##### Sequential Access

Specify the RB\$SEQ code in the 1-byte RAC field of the RAB.

##### Record

Specify the address of the record to be transferred in the 1-word RBF field of the RAB, and the size (in bytes) of the record in the 1-word RSZ field of the RAB.

If the record is in VFC format, specify the address of the fixed-length portion of the record in the 1-word RHB field of the RAB. If you specify 0 in this field, the record header will be null-filled.

**OPERATION MACRO DESCRIPTIONS**  
**\$PUT MACRO (SEQUENTIAL ACCESS)**

**Locate Mode**

For a sequential file, if you want the PUT operation to use locate mode, specify the address of the user buffer in the 1-word UBF field of the RAB, specify the maximum size of the record for the next PUT operation in the 1-word USZ field of the RAB, and set the RB\$LOC mask in the 1-word ROP field of the RAB.

The PUT operation returns (in the RBF field) the address of a location where your program can build the next record for output. The maximum next record size that you specify in the USZ field determines whether the next record can fit into an I/O buffer.

**Bucket Fill Number Honoring**

If you want the PUT operation to honor bucket fill numbers for the file and its areas, set the RB\$LOA mask in the 1-word ROP field of the RAB. If you do not set this mask, the PUT operation fills buckets without regard to bucket fill numbers.

**Update Existing Record (Relative File)**

If you want to transfer the record to a cell in a relative file even if the cell contains a record, set the RB\$UIF mask in the 1-word ROP field of the RAB. If you do not set this mask, and if the cell already contains a record, the PUT operation returns an error completion and does not transfer the record.

**Mass Insertion (Indexed File)**

For an indexed file, using mass-insertion mode for a series of PUT operations speeds up the insertion of a series of records. To use mass-insertion mode for a series of records, set the RB\$MAS mask in the 1-word ROP field of the RAB for each PUT operation in the series.

**STREAM CONTEXT**

The current-record and next-record contexts after a sequential access PUT operation are undefined.

**RETURNED VALUES**

**Next Record Buffer**

If you specified locate mode for the PUT operation, the PUT operation returns the address of a location where your program can build the next record for output in the 1-word RBF field of the RAB. This address gives a location in the I/O buffer (if there is room for another record there), or the location of your user buffer (if not).

**RRN**

For a relative file or for a sequential disk file with fixed-length records, a sequential-access PUT operation returns the relative record number (RRN) for the inserted record in the 2-word BKT field of the RAB.

**RFA**

The PUT operation returns the record file address (RFA) for the inserted record in the 3-word RFA field of the RAB.

**Completion Status and Value**

The PUT operation returns completion status in the 1-word STS field of the RAB and returns a completion value in the 1-word STV field of the RAB. Appendix A lists completion status symbols and values.

**CHECKLISTS**

Table 5-37 lists control block fields that are input to the PUT operation. Table 5-38 lists control block fields that are output by the PUT operation.

Table 5-37: PUT (Sequential Access) Input Fields

Block Field	Description
RAB ISI	Internal stream identifier
RAB RAC	Record access code
	RB\$SEQ Sequential access
RAB RBF	Record buffer address
RAB RHB	VFC control buffer address
RAB ROP	Record processing option mask
	RB\$LOA Honor bucket fill numbers
	RB\$LOC Locate mode
	RB\$MAS Mass insert
	RB\$UIF Update if record exists
RAB RSZ	Record size (bytes)
RAB UBF	User buffer address
RAB USZ	User buffer size (bytes)

Table 5-38: PUT (Sequential Access) Output Fields

Block Field	Description
RAB BKT	Relative record number (RRN)
RAB RFA	Record file address
RAB RBF	Record buffer address
RAB STS	Completion status code
RAB STV	Completion status value

**OPERATION MACRO DESCRIPTIONS**  
**\$PUT MACRO (KEY ACCESS)**

**5.20 \$PUT MACRO (KEY ACCESS)**

The \$PUT macro calls the PUT operation routine to transfer a record from a user buffer to an I/O buffer and to a sequential disk file (with fixed-length records), a relative file, or an indexed file.

The target of a key-access PUT operation depends on the file organization:

- For a sequential disk file (with fixed-length records) or a relative file, the key is a relative record number (RRN), and the target of a key-access PUT operation is the cell specified by the RRN.
- For an indexed file, a key-access PUT operation has no target; the PUT operation inserts the record and updates indexes.

**FORMAT**

The format for the \$PUT is:

```
$PUT rabaddr[, [erraddr][, sucaddr]]
```

where rabaddr is the address of the RAB for the operation; erraddr is the address of the error handler for the operation; and sucaddr is the address of the success handler for the operation.

**CONTROL BLOCKS**

You must supply a RAB for the PUT operation.

**OPTIONS**

**Internal Stream Identifier**

The PUT operation reads the internal stream identifier from the 1-word ISI field of the RAB.

**Key Access**

Specify the RB\$KEY code in the 1-byte RAC field of the RAB.

**Record**

Specify the address of the record to be transferred in the 1-word RBF field of the RAB, and the size (in bytes) of the record in the 1-word RSZ field of the RAB.

If the record is in VFC format, specify the address of the fixed-length portion of the record in the 1-word RHB field of the RAB. If you specify 0 in this field, the record header will be null-filled.

**Record Buffer**

Specify a record buffer for the PUT operation; specify the address of the record buffer in the 1-word UBF field of the RAB; specify the size (in bytes) of the record buffer in the 1-word USZ field of the RAB.

Note that the value in the UBF field will be used (copied to the RBF field) only if you specify locate mode. A request for locate mode is otherwise ignored for a key access PUT operation.

#### RRN

For a relative file or for a sequential disk file with fixed-length records, specify a 4-byte relative record number (RRN) in the 1-word KBF field of the RAB, and specify 0 or 4 in the 1-byte KSZ field of the RAB.

#### Bucket Fill Number Honoring

If you want the PUT operation to honor bucket fill numbers for the file and its areas, set the RB\$LOA mask in the 1-word ROP field of the RAB. If you do not set this mask, the PUT operation fills buckets without regard to bucket fill numbers.

#### Update Existing Record (Relative File)

If you want to transfer the record to a cell in a relative file even if the cell contains a record, set the RB\$UIF mask in the 1-word ROP field of the RAB. If you do not set this mask, and if the cell already contains a record, the PUT operation returns an error completion and does not transfer the record.

#### STREAM CONTEXT

The current-record context after a key access PUT operation is undefined; the next-record context is unchanged.

#### RETURNED VALUES

##### RRN

For a relative file or for a sequential disk file with fixed-length records, a key-access PUT operation returns the relative record number (RRN) for the inserted record in the 2-word BKT field of the RAB.

##### RFA

The PUT operation returns the record file address (RFA) for the inserted record in the 3-word RFA field of the RAB.

#### Completion Status and Value

The PUT operation returns completion status in the 1-word STS field of the RAB and returns a completion value in the 1-word STV field of the RAB. Appendix A lists completion status symbols and values.

#### CHECKLISTS

Table 5-39 lists control block fields that are input to the PUT operation. Table 5-40 lists control block fields that are output by the PUT operation.

OPERATION MACRO DESCRIPTIONS  
 \$PUT MACRO (KEY ACCESS)

Table 5-39: PUT (Key Access) Input Fields

Block	Field	Description
RAB	ISI	Internal stream identifier
RAB	KBF	Key buffer address
RAB	KSZ	Key size (bytes)

RAB	STV	Completion status value

## 5.21 \$READ MACRO (SEQUENTIAL ACCESS)

The \$READ macro calls the READ operation routine to transfer blocks from a file to an I/O buffer. The target of a sequential-access READ operation is the readable block (and, for a multiblock READ operation, following blocks).

### FORMAT

The format for the \$READ is:

```
$READ rabaddr[, [erraddr][, sucaddr]]
```

where rabaddr is the address of the RAB for the operation; erraddr is the address of the error handler for the operation; and sucaddr is the address of the success handler for the operation.

### CONTROL BLOCKS

You must supply a RAB for the READ operation.

### OPTIONS

#### Internal Stream Identifier

The READ operation reads the internal stream identifier from the 1-word ISI field of the RAB.

#### Block Specification

For a sequential-access READ operation, specify 0 in the 2-word BKT field of the RAB.

#### User Buffer

Specify the address of the user buffer in the 1-word UBF field of the RAB, and specify the size (in bytes) of the user buffer in the 1-word USZ field of the RAB.

For a magtape file, the READ operation reads at most one magtape block into the buffer; for other files, the READ operation fills the buffer (unless it reached the end-of-file before the buffer is filled).

### STREAM CONTEXT

The readable-block context after a READ operation is the block following the last-read block; the writable-block context is the first-read block.

OPERATION MACRO DESCRIPTIONS  
\$READ MACRO (SEQUENTIAL ACCESS)

RETURNED VALUES

Data Blocks

The READ operation returns the address and length of the data read from the file. The value in the 1-word RBF field of the RAB is the address of the data read; the value in the 1-word RSZ field of the RAB is the length (in bytes) of the data read.

The READ operation normally will not read beyond the logical end-of-file. For sequential files with undefined (UDF) record format, however, the READ operation will respect the logical end-of-file marker only if you have specified no write-sharing in the 1-byte SHR field of the FAB. If you specify write-sharing, RMS-11 will ignore the logical end-of-file marker and will stop only at the physical end-of-file on the disk.

Record File Address (RFA)

The READ operation returns the virtual block number of the first-read block in the first two words of the 3-word RFA field of the RAB (it clears the third word).

Completion Status and Value

The READ operation returns completion status in the 1-word STS field of the RAB and returns a completion value in the 1-word STV field of the RAB. Appendix A lists completion status symbols and values.

CHECKLISTS

Table 5-41 lists control block fields that are input to the READ operation. Table 5-42 lists control block fields that are output by the READ operation.

Table 5-41: READ (Sequential Access) Input Fields

Block	Field	Description
RAB	BKT	Virtual block number (VBN)
RAB	ISI	Internal stream identifier
RAB	UBF	User buffer address
RAB	USZ	User buffer size (bytes)

Table 5-42: READ (Sequential Access) Output Fields

Block	Field	Description
RAB	RBF	Record buffer address
RAB	RFA	Virtual block number (2 words)
RAB	RSZ	Record size (bytes)
RAB	STS	Completion status code
RAB	STV	Completion status value

## 5.22 \$READ MACRO (VBN ACCESS)

The \$READ macro calls the READ operation routine to transfer blocks from a file to an I/O buffer. The target of a VBN-access READ operation is a specified block (and, for a multiblock READ operation, following blocks).

### FORMAT

The format for the \$READ is:

```
$READ rabaddr[, [erraddr][, sucaddr]]
```

where rabaddr is the address of the RAB for the operation; erraddr is the address of the error handler for the operation; and sucaddr is the address of the success handler for the operation.

### CONTROL BLOCKS

You must supply a RAB for the READ operation.

### OPTIONS

#### Internal Stream Identifier

The READ operation reads the internal stream identifier from the 1-word ISI field of the RAB.

#### Block Specification

Specify the virtual block number of the first block to be read in the 2-word BKT field of the RAB.

#### User Buffer

Specify the address of the user buffer in the 1-word UBF field of the RAB, and specify the size (in bytes) of the user buffer in the 1-word USZ field of the RAB.

For a magtape file, the READ operation reads at most one magtape block into the buffer; for other files, the READ operation fills the buffer (unless it reached the end-of-file before the buffer is filled).

### STREAM CONTEXT

The readable-block context after a READ operation is the block following the last-read block; the writable-block context is the first-read block.

OPERATION MACRO DESCRIPTIONS  
\$READ MACRO (VBN ACCESS)

RETURNED VALUES

Data Blocks

The READ operation returns the address and length of the data read from the file. The value in the 1-word RBF field of the RAB is the address of the data read; the value in the 1-word RSZ field of the RAB is the length (in bytes) of the data read.

The READ operation normally will not read beyond the logical end-of-file. For sequential files with undefined (UDF) record format, however, the READ operation will respect the logical end-of-file marker only if you have specified no write-sharing in the 1-byte SHR field of the FAB. If you specify write-sharing, RMS-11 will ignore the logical end-of-file marker and will stop only at the physical end-of-file on the disk.

Record File Address (RFA)

The READ operation returns the virtual block number of the first-read block in the first two words of the 3-word RFA field of the RAB (it clears the third word).

Completion Status and Value

The READ operation returns completion status in the 1-word STS field of the RAB and returns a completion value in the 1-word STV field of the RAB. Appendix A lists completion status symbols and values.

CHECKLISTS

Table 5-43 lists control block fields that are input to the READ operation. Table 5-44 lists control block fields that are output by the READ operation.

Table 5-43: READ (VBN Access) Input Fields

Block Field	Description
RAB BKT	Virtual block number (VBN)
RAB ISI	Internal stream identifier
RAB UBF	User buffer address
RAB USZ	User buffer size (bytes)

Table 5-44: READ (VBN Access) Output Fields

Block Field	Description
RAB RBF	Record buffer address
RAB RFA	Virtual block number (2 words)
RAB RSZ	Record size (bytes)
RAB STS	Completion status code
RAB STV	Completion status value

### 5.23 \$RENAME MACRO

The \$RENAME macro calls the RENAME operation routine to change the directory entry for a file.

The old and new entries (file specifications) must have the same network node and device specifications.

#### FORMAT

The format for the \$RENAME is:

```
$RENAME oldfabaddr,[erraddr],[sucaddr],newfabaddr
```

where oldfabaddr is the address of the FAB for the operation; erraddr is the address of the error handler for the operation; sucaddr is the address of the success handler for the operation; and newfabaddr is the address of the FAB giving the new file specification.

#### CONTROL BLOCKS

You must supply two FABs for the RENAME operation: an "old" FAB containing the current specification for the file, and a "new" FAB containing the new specification for the file.

If you supply a NAM block for the old FAB (old NAM block) and specify either rename by NAM block or wildcarding, the RENAME operation reads its fields to obtain identifiers for the old file specification. If you supply a NAM block for the new FAB (new NAM block) and specify rename by NAM block, the RENAME operation reads its fields to obtain identifiers for the new file specification.

To supply a NAM block for the RENAME operation, specify the address of the NAM block in the 1-word NAM field of the FAB.

To supply XABs (ALL, DAT, KEY, PRO, and SUM blocks) for the RENAME operation, specify the address of the first XAB in the 1-word XAB field of the FAB; specify the address of the next XAB (if any) in the 1-word NXT field of each XAB; specify 0 in the NXT field of the last XAB.

All KEY blocks must be together in the chain of XABs, and must be in ascending order (by the index reference number in the 1-byte REF field of the KEY block); the index reference numbers need not be consecutive.

All ALL blocks must be together in the chain of XABs, and must be in ascending order (by the area identifier in the 1-byte AID field of the ALL block); the area identifiers need not be consecutive.

Multiple DAT, PRO, or SUM XABs are illegal.

#### OPTIONS

##### Old File Specification (Nonwildcard RENAME Operation)

The RENAME operation constructs the full file specification from the file string, the default string (which contributes only elements not present in the file string), and RMS-11 defaults (which contribute elements not present in either the file string or the default string).

**OPERATION MACRO DESCRIPTIONS**  
**\$RENAME MACRO**

RMS-11 defaults are:

- Device -- The device to which the specified logical channel is assigned, or SY: if the specified logical channel is not assigned to any device.
- Directory -- The current directory for the task.
- Name, type, -- Defaulted to null.

The file string and the default string must not contain wildcards.

Specify the address of the file string in the 1-word FNA field of the FAB. Specify the size (in bytes) of the file string in the 1-byte FNS field of the FAB; if you specify 0 in the FNS field, the RENAME operation uses no file string.

Specify the address of the default string in the 1-word DNA field of the FAB. Specify the size (in bytes) of the default string in the 1-byte DNS field of the FAB; if you specify 0 in the DNS field, the RENAME operation uses no default string.

If you set the FB\$FID mask in the 1-word FOP field of the FAB and supply a NAM block, the RENAME operation reads the device identifier from the 2-word DVI field of the NAM block; if this value is nonzero, the specified device overrides the device in the merged string.

**Old File Specification (Wildcard RENAME Operation)**

You can use the RENAME operation in a wildcarding program loop. (The NB\$WCH mask in the 1-word FNB field of the NAM block will already have been set by an earlier PARSE operation.)

If you set the FB\$FID mask in the 1-word FOP field of the FAB, the file found by a previous SEARCH operation is renamed without affecting fields that are used as context for subsequent SEARCH operations.

If you clear the FB\$FID mask in the 1-word FOP field of the FAB, the RENAME operation first performs an implicit SEARCH operation. (The input and output fields for the SEARCH operation are not described here and are not included in the checklists at the end of this section.)

If the SEARCH operation finds a file that matches the wildcard file specification, the RENAME operation replaces its directory entry; if not, the RENAME operation does not replace a directory entry, but instead passes control block data from the SEARCH operation (in particular, the ER\$NMF completion status code and the cleared NB\$WCH mask in the 1-word FNB field of the NAM block).

**New File Specification**

The RENAME operation constructs the full file specification from the file string, the default string (which contributes only elements not present in the file string), and RMS-11 defaults (which contribute elements not present in either the file string or the default string).

RMS-11 defaults are:

- Device -- The device that was used for the old file specification (The old FAB logical channel is used, and the new FAB logical channel is ignored).

- Directory -- The current directory for the task.
- Name, type, -- Defaulted to null.

The file string and the default string must not contain wildcards.

Specify the address of the file string in the 1-word FNA field of the FAB. Specify the size (in bytes) of the file string in the 1-byte FNS field of the FAB; if you specify 0 in the FNS field, the RENAME operation uses no file string.

Specify the address of the default string in the 1-word DNA field of the FAB. Specify the size (in bytes) of the default string in the 1-byte DNS field of the FAB; if you specify 0 in the DNS field, the RENAME operation uses no default string.

If you set the FB\$FID mask in the 1-word FOP field of the FAB and supply a NAM block, the RENAME operation reads the device identifier from the 2-word DVI field of the NAM block; if this value is nonzero, the specified device overrides the device in the merged string.

#### Private Buffer Pool

If you want the RENAME operation to use a private buffer pool instead of the central buffer pool, specify the address of the (word-aligned) private buffer pool in the 1-word BPA field of the FAB, and its size (in bytes) in the 1-word BPS field of the FAB; this size must be a multiple of 4.

If you specify 0 in either the BPA field or the BPS field, the RENAME operation uses the central buffer pool.

#### Logical Channel

Specify the logical channel for the RENAME operation in the 1-byte LCH field of the FAB. The logical channel number must not be the same as the logical channel number for any already-open file, and must not be 0.

#### Expanded String Buffers

If you want the expanded string for the file given by a FAB returned to a buffer, supply a NAM block for the FAB. Specify the address of the buffer in the 1-word ESA field of the NAM block, and the size (in bytes) of the buffer in the 1-byte ESS field of the NAM block. If you do not supply a NAM block for a FAB, or if you specify 0 in the ESS field, the RENAME operation does not return the expanded string.

**OPERATION MACRO DESCRIPTIONS**  
**\$RENAME MACRO**

**RETURNED VALUES**

**Expanded Strings**

If you specify a buffer for the expanded string for a FAB (ESA and ESS fields in the NAM block), the RENAME operation writes the expanded string in the buffer, and writes the length (in bytes) of the string in the 1-byte ESL field of the NAM block.

**Device Characteristics**

The RENAME operation returns device characteristics as masks in the 1-byte DEV field of the FAB. The device characteristics are:

- Printer or terminal (indicated by the set FB\$CCL mask in the 1-byte DEV field of the FAB and the set FB\$REC mask in the 1-byte DEV field of the FAB; for a terminal, the FB\$TRM mask in the 1-byte DEV field of the FAB is also set); RMS-11 treats a printer or terminal as a unit-record device.
- Disk, DECTape, or DECTAPE II (indicated by the set FB\$MDI mask in the 1-byte DEV field of the FAB); RMS-11 treats a disk, DECTape, or DECTAPE II as a disk device.
- Unit-record device (indicated by the set FB\$REC mask in the 1-byte DEV field of the FAB).
- Non-ANSI magtape or cassette tape (indicated by the set FB\$SDI mask in the 1-byte DEV field of the FAB and the set FB\$REC mask in the 1-byte DEV field of the FAB); RMS-11 treats a non-ANSI magtape or a cassette tape as a unit-record device.
- ANSI-format magtape (indicated by the set FB\$SQD mask in the 1-byte DEV field of the FAB).

**Device and File Identifiers**

If you supply a NAM block, the RENAME operation writes a device identifier in the 2-word DVI field of the NAM block and a file identifier in the 3-word FID field of the NAM block.

**File Specification Characteristics**

The RENAME operation sets masks in the 1-word FNB field of the NAM block to show which file specification elements were present in the file string and default string.

These masks and their meaning are:

NB\$NOD	Node in file string or default string
NB\$DEV	Device in file string or default string
NB\$DIR	Directory in file string or default string
NB\$QUO	Quoted string in file string or default string
NB\$NAM	File name in file string or default string
NB\$TYP	File type in file string or default string
NB\$VER	File version in file string or default string
NB\$WDI	Wildcard directory in file string or default string
NB\$WNA	Wildcard file name in file string or default string
NB\$WTY	Wildcard file type in file string or default string
NB\$WVE	Wildcard file version in file string or default string

**Wildcarding**

The RENAME operation clears the NB\$WCH mask in the 1-word FNB field of the NAM block; this shows that no wildcard context exists after the RENAME operation. It also clears the 1-byte RSL field of the NAM block to show that no resultant string was returned.

**Completion Status and Value**

The RENAME operation returns completion status in the 1-word STS field of the FAB and returns a completion value in the 1-word STV field of the FAB. Appendix A lists completion status symbols and values.

**CHECKLISTS**

Table 5-45 lists control block fields that are input to the RENAME operation. Table 5-46 lists control block fields that are output by the RENAME operation.

**NOTE**

The only input fields taken from both the "old" and the "new" FABs are the DNA, DNS, FNA, FNS, FOP, and NAM fields. All other FAB input fields are taken from the "old" FAB only. All FAB output fields are returned to the "old" FAB only.

**Table 5-45: RENAME Input Fields**

Block	Field	Description
ALL	NXT	Next XAB address
DAT	NXT	Next XAB address
FAB	BPA	Private buffer pool address
FAB	BPS	Private buffer pool size (bytes)
FAB	DNA	Default string address
FAB	DNS	Default string size (bytes)
FAB	FNA	File string address
FAB	FNS	File string size (bytes)
FAB	FOP	File processing option mask
		FB\$FID Use information in NAM block
FAB	LCH	Logical channel number
FAB	NAM	NAM block address
KEY	NXT	Next XAB address
NAM	DVI	Device identifier
NAM	ESA	Expanded string buffer address
NAM	ESS	Expanded string buffer size (bytes)
NAM	FNB	File specification mask
		NB\$WCH Wildcard context established
PRO	NXT	Next XAB address
SUM	NXT	Next XAB address

OPERATION MACRO DESCRIPTIONS  
\$RENAME MACRO

Table 5-46: RENAME Output Fields

Block	Field	Description
FAB	DEV	Device characteristic mask
	FB\$CCL	Carriage-control device
	FB\$MDI	Multidirectory device
	FB\$REC	Record-oriented device
	FB\$SDI	Single-directory device
	FB\$SQD	Sequential device
	FB\$TRM	Terminal device
FAB	STS	Completion status code
FAB	STV	Completion status value
NAM	DVI	Device identifier
NAM	ESL	Expanded string length (bytes)
NAM	FID	File identifier
NAM	FNB	File specification mask
	NB\$NOD	Node in file string or default string
	NB\$DEV	Device in file string or default string
	NB\$DIR	Directory in file string or default string
	NB\$QUO	Quoted string in file string or default string
	NB\$NAM	File name in file string or default string
	NB\$TYP	File type in file string or default string
	NB\$VER	File version in file string or default string
	NB\$WDI	Wildcard directory in file string or default string
	NB\$WNA	Wildcard file name in file string or default string
	NB\$WTY	Wildcard file type in file string or default string
	NB\$WVE	Wildcard file version in file string or default string
	NB\$WCH	Wildcard context established (cleared)
NAM	RSL	Resultant string length (bytes)

## 5.24 \$REWIND MACRO

The \$REWIND macro calls the REWIND operation routine to reset the context for a stream to the beginning-of-file. The file can have any organization.

The file cannot be on a magtape device.

### FORMAT

The format for the \$REWIND is:

```
$REWIND rabaddr[, [erraddr][, sucaddr]]
```

where rabaddr is the address of the RAB for the operation; erraddr is the address of the error handler for the operation; and sucaddr is the address of the success handler for the operation.

### CONTROL BLOCKS

You must supply a RAB for the REWIND operation.

### OPTIONS

#### Internal Stream Identifier

The REWIND operation reads the internal stream identifier from the 1-word ISI field of the RAB.

#### Key of Reference

For an indexed file, you must specify the index that the stream will use in accessing records. Specify this key of reference in the 1-byte KRF field of the RAB. This value matches the value in the file's KEY block for the index: 0 for the primary index, 1 for the first alternate index, and so forth.

### STREAM CONTEXT

For a record access file, the current context after a REWIND operation is undefined and the next-record context is the first record in the file; for an indexed file, this first record is defined by the specified index.

For a block access file, both the readable-block and writable-block contexts after a REWIND operation are the first block in the file.

### RETURNED VALUES

#### Completion Status and Value

The REWIND operation returns completion status in the 1-word STS field of the RAB and returns a completion value in the 1-word STV field of the RAB. Appendix A lists completion status symbols and values.

OPERATION MACRO DESCRIPTIONS  
\$REWIND MACRO

CHECKLISTS

Table 5-47 lists control block fields that are input to the REWIND operation. Table 5-48 lists control block fields that are output by the REWIND operation.

Table 5-47: REWIND Input Fields

Block Field	Description
RAB ISI	Internal stream identifier
RAB KRF	Key of reference

Table 5-48: REWIND Output Fields

Block Field	Description
RAB STS	Completion status code
RAB STV	Completion status value

## 5.25 \$SEARCH MACRO

The \$SEARCH macro calls the SEARCH operation routine to scan a directory and return a file specification and identifiers in NAM block fields. You should precede the SEARCH operation by a PARSE operation, which initializes the NAM block fields for the SEARCH operation.

The SEARCH operation finds a file specification that matches the match-pattern initialized (in the expanded string buffer) by the PARSE operation; a series of wildcard SEARCH operations returns successive matching file specifications.

### FORMAT

The format for the \$SEARCH is:

```
$SEARCH fabaddr[, [erraddr][, sucaddr]]
```

where fabaddr is the address of the FAB for the operation; erraddr is the address of the error handler for the operation; and sucaddr is the address of the success handler for the operation.

### CONTROL BLOCKS

You must supply a FAB for the SEARCH operation.

You must supply a NAM block for the SEARCH operation.

To supply a NAM block for the SEARCH operation, specify the address of the NAM block in the 1-word NAM field of the FAB.

To supply XABs (ALL, DAT, KEY, PRO, and SUM blocks) for the SEARCH operation, specify the address of the first XAB in the 1-word XAB field of the FAB; specify the address of the next XAB (if any) in the 1-word NXT field of each XAB; specify 0 in the NXT field of the last XAB.

All KEY blocks must be together in the chain of XABs, and must be in ascending order (by the index reference number in the 1-byte REF field of the KEY block); the index reference numbers need not be consecutive.

All ALL blocks must be together in the chain of XABs, and must be in ascending order (by the area identifier in the 1-byte AID field of the ALL block); the area identifiers need not be consecutive.

Multiple DAT, PRO, or SUM XABs are illegal.

### OPTIONS

#### Wildcard Context Information

The SEARCH operation reads NAM block fields that are initialized, written, or preserved by a preceding PARSE or wildcard SEARCH operation: the 2-word DVI field of the NAM block, the 1-word ESA field of the NAM block, the 1-byte ESL field of the NAM block, the NB\$WCH mask in the 1-word FNB field of the NAM block, the 1-word RSA field of the NAM block, the 1-byte RSL field of the NAM block, the 1-byte RSS field of the NAM block, the 1-word WCC field of the NAM block, and the 1-word WDI field of the NAM block.

## OPERATION MACRO DESCRIPTIONS

### \$SEARCH MACRO

The SEARCH operation also uses the expanded string in the expanded string buffer.

You must preserve these fields between a PARSE and a SEARCH operation and between successive wildcard SEARCH operations.

#### Private Buffer Pool

If you want the SEARCH operation to use a private buffer pool instead of the central buffer pool, specify the address of the (word-aligned) private buffer pool in the 1-word BPA field of the FAB, and its size (in bytes) in the 1-word BPS field of the FAB; this size must be a multiple of 4.

If you specify 0 in either the BPA field or the BPS field, the SEARCH operation uses the central buffer pool.

#### Logical Channel

Specify the logical channel for the SEARCH operation in the 1-byte LCH field of the FAB. The logical channel number must not be the same as the logical channel number for any already-open file, and must not be 0.

#### Magtape Positioning

The FB\$RWO mask in the 1-word FOP field of the FAB and the FB\$RWC mask in the 1-word FOP field of the FAB should not be set during wildcard SEARCH operations on magtape to avoid unpredictable results. The first SEARCH operation on a magtape will rewind the tape automatically.

#### RETURNED VALUES

##### Resultant String

The SEARCH operation writes the full file specification for the found file in the resultant string buffer, and writes the length of the string in the 1-byte RSL field of the NAM block.

##### Device Characteristics

The SEARCH operation returns device characteristics as masks in the 1-byte DEV field of the FAB. The device characteristics are:

- Printer or terminal (indicated by the set FB\$CCL mask in the 1-byte DEV field of the FAB and the set FB\$REC mask in the 1-byte DEV field of the FAB; for a terminal, the FB\$TRM mask in the 1-byte DEV field of the FAB is also set); RMS-11 treats a printer or terminal as a unit-record device.
- Disk, DECTape, or DECTAPE II (indicated by the set FB\$MDI mask in the 1-byte DEV field of the FAB); RMS-11 treats a disk, DECTape, or DECTAPE II as a disk device.
- Unit-record device (indicated by the set FB\$REC mask in the 1-byte DEV field of the FAB).

- Non-ANSI magtape or cassette tape (indicated by the set FB\$SDI mask in the 1-byte DEV field of the FAB and the set FB\$REC mask in the 1-byte DEV field of the FAB); RMS-11 treats a non-ANSI magtape or a cassette tape as a unit-record device.
- ANSI-format magtape (indicated by the set FB\$SQD mask in the 1-byte DEV field of the FAB).

#### File Identifier

If the SEARCH operation finds a file that matches the wildcard pattern, and the FB\$FID mask in the 1-word FOP field of the FAB is set, it writes the file identifier for the found file in the 3-word FID field of the NAM block.

In addition, when using SEARCH with ANSI magtapes, the presence of the FB\$FID mask signifies wildcarding "with intent to open." This causes RMS-11 to use special magtape wildcarding (see the RSTS/E Programming Manual). If the FB\$FID mask is not set, normal magtape wildcarding is used.

#### Wildcard Context Information

The SEARCH operation writes the wildcard context in the 1-word WCC field of the NAM block, and the wildcard directory context in the 1-word WDI field of the NAM block.

If the SEARCH operation did not find a matching file, it clears the NB\$WCH mask in the 1-word FNB field of the NAM block; this shows that no further wildcarding is possible using the current wildcard information.

#### Completion Status and Value

The SEARCH operation returns completion status in the 1-word STS field of the FAB and returns a completion value in the 1-word STV field of the FAB. Appendix A lists completion status symbols and values.

#### CHECKLISTS

Table 5-49 lists control block fields that are input to the SEARCH operation. Table 5-50 lists control block fields that are output by the SEARCH operation.

Table 5-49: SEARCH Input Fields

Block	Field	Description
ALL	NXT	Next XAB address
DAT	NXT	Next XAB address
FAB	BPA	Private buffer pool address
FAB	BPS	Private buffer pool size (bytes)

(Continued on next page)

OPERATION MACRO DESCRIPTIONS  
 \$SEARCH MACRO

Table 5-49 (Cont.): SEARCH Input Fields

Block	Field	Description
FAB	FOP	File processing option mask
	FB\$FID	Use information in NAM block
	FB\$RWO	Rewind magtape before operation
	FB\$RWC	Rewind magtape after closing file
FAB	LCH	Logical channel number
FAB	NAM	NAM block address
KEY	NXT	Next XAB address
NAM	DVI	Device identifier
NAM	ESA	Expanded string buffer address
NAM	ESL	Expanded string length (bytes)
NAM	FNB	File specification mask
	NB\$WCH	Wildcard context established
NAM	RSA	Resultant string buffer address
NAM	RSL	Resultant string length (bytes)
NAM	RSS	Resultant string buffer size (bytes)
NAM	WCC	Wildcard context
NAM	WDI	Wildcard directory context
PRO	NXT	Next XAB address
SUM	NXT	Next XAB address

Block	Field	Description
FAB	DEV	Device characteristic mask
	FB\$CCL	Carriage-control device
	FB\$MDI	Multidirectory device
	FB\$REC	Record-oriented device
	FB\$SDI	Single-directory device
	FB\$SQD	Sequential device
	FB\$TRM	Terminal device
FAB	STS	Completion status code
FAB	STV	Completion status value
NAM	FID	File identifier
NAM	FNB	File specification mask
	NB\$WCH	Wildcard context established
NAM	RSL	Resultant string length (bytes)
NAM	WCC	Wildcard context
NAM	WDI	Wildcard directory context

## 5.26 \$TRUNCATE MACRO

The \$TRUNCATE macro calls the TRUNCATE operation routine to remove records from the latter part of a sequential file; records are removed inclusively from the current record through the end-of-file. If the file cannot be truncated, the TRUNCATE operation returns an error completion and leaves the current-record context undefined and the next-record context unchanged.

### FORMAT

The format for the \$TRUNCATE is:

```
$TRUNCATE rabaddr[, [erraddr] [, sucaddr]]
```

where rabaddr is the address of the RAB for the operation; erraddr is the address of the error handler for the operation; and sucaddr is the address of the success handler for the operation.

### CONTROL BLOCKS

You must supply a RAB for the TRUNCATE operation.

### OPTIONS

#### Internal Stream Identifier

The TRUNCATE operation reads the internal stream identifier from the 1-word ISI field of the RAB.

### STREAM CONTEXT

The TRUNCATE operation destroys the current-record context; the next-record context after the TRUNCATE operation is the end-of-file.

### RETURNED VALUES

#### Completion Status and Value

The TRUNCATE operation returns completion status in the 1-word STS field of the RAB and returns a completion value in the 1-word STV field of the RAB. Appendix A lists completion status symbols and values.

### CHECKLISTS

Table 5-51 lists control block fields that are input to the TRUNCATE operation. Table 5-52 lists control block fields that are output by the TRUNCATE operation.

OPERATION MACRO DESCRIPTIONS  
\$TRUNCATE MACRO

Table 5-51: TRUNCATE Input Fields

Block	Field	Description
RAB	ISI	Internal stream identifier

Table 5-52: TRUNCATE Output Fields

Block	Field	Description
RAB	STS	Completion status code
RAB	STV	Completion status value

## 5.27 \$UPDATE MACRO

The \$UPDATE macro calls the UPDATE operation routine to transfer a record from a user buffer to a disk file (overwriting the existing record). The target of the UPDATE operation is the current record, which is overwritten.

If no record (as specified in the RAB) can be transferred, the UPDATE operation returns an error completion.

### FORMAT

The format for the \$UPDATE is:

```
$UPDATE rabaddr[, [erraddr][, sucaddr]]
```

where rabaddr is the address of the RAB for the operation; erraddr is the address of the error handler for the operation; and sucaddr is the address of the success handler for the operation.

### CONTROL BLOCKS

You must supply a RAB for the UPDATE operation.

### OPTIONS

#### Internal Stream Identifier

The UPDATE operation reads the internal stream identifier from the 1-word ISI field of the RAB.

#### Record Buffer

Specify the address of the record buffer in the 1-word RBF field of the RAB, and specify the size (in bytes) of the record buffer in the 1-word RSZ field of the RAB. For sequential files and for indexed files in which duplicate primary key values are permitted, the size of the buffer must be the same as the size of the existing record.

If the file has VFC format, specify the address of the buffer for the VFC header in the 1-word RHB field of the RAB; if you specify zero in this field, the existing record header will remain unchanged.

#### Bucket Fill Number Honoring

If you want the UPDATE operation to honor bucket fill numbers for the file and its areas, set the RB\$LOA mask in the 1-word ROP field of the RAB. If you do not set this mask, the UPDATE operation fills buckets without regard to bucket fill numbers.

### STREAM CONTEXT

The UPDATE operation destroys the current-record context; the next-record context after the UPDATE operation is unchanged.

OPERATION MACRO DESCRIPTIONS  
\$UPDATE MACRO

RETURNED VALUES

Completion Status and Value

The UPDATE operation returns completion status in the 1-word STS field of the RAB and returns a completion value in the 1-word STV field of the RAB. Appendix A lists completion status symbols and values.

CHECKLISTS

Table 5-53 lists control block fields that are input to the UPDATE operation. Table 5-54 lists control block fields that are output by the UPDATE operation.

Table 5-53: UPDATE Input Fields

Block Field	Description
RAB ISI	Internal stream identifier
RAB RBF	Record buffer address
RAB RHB	VFC control buffer address
RAB ROP	Record processing option mask
	RB\$LOA Honor bucket fill numbers
RAB RSZ	Record size (bytes)

Table 5-54: UPDATE Output Fields

Block Field	Description
RAB STS	Completion status code
RAB STV	Completion status value

## 5.28 \$WRITE MACRO (SEQUENTIAL ACCESS)

The \$WRITE macro calls the WRITE operation routine to write blocks to a file. The target of a sequential-access WRITE operation is the writable block (and, for a multiblock WRITE operation, following blocks).

### FORMAT

The format for the \$WRITE is:

```
$WRITE rabaddr[, [erraddr] [, sucaddr]]
```

where rabaddr is the address of the RAB for the operation; erraddr is the address of the error handler for the operation; and sucaddr is the address of the success handler for the operation.

### CONTROL BLOCKS

You must supply a RAB for the WRITE operation.

### OPTIONS

#### Internal Stream Identifier

The WRITE operation reads the internal stream identifier from the 1-word ISI field of the RAB.

#### Block Identification

For a sequential-access WRITE operation, specify 0 in the 2-word BKT field of the RAB.

#### Record Buffer

Specify the address of the record buffer in the 1-word RBF field of the RAB, and specify the size (in bytes) of the record buffer in the 1-word RSZ field of the RAB. You must specify a record buffer for the WRITE operation; the WRITE operation transfers data from this buffer to the file.

The WRITE operation normally updates the logical end-of-file marker, when appropriate. For sequential files with undefined (UDF) record format, however, the WRITE operation updates the logical end-of-file marker only if no write-sharing has been specified in the 1-byte SHR field of the FAB.

### STREAM CONTEXT

The readable-block context after a WRITE operation is the block following the last-written block; the writable-block context after a WRITE operation is the block following the last-written block.

OPERATION MACRO DESCRIPTIONS  
\$WRITE MACRO (SEQUENTIAL ACCESS)

RETURNED VALUES

Record File Address (RFA)

The WRITE operation returns the virtual block number of the first-written block in the first two words of the 3-word RFA field of the RAB (it clears the third word).

Completion Status and Value

The WRITE operation returns completion status in the 1-word STS field of the RAB and returns a completion value in the 1-word STV field of the RAB. Appendix A lists completion status symbols and values.

CHECKLISTS

Table 5-55 lists control block fields that are input to the WRITE operation. Table 5-56 lists control block fields that are output by the WRITE operation.

Table 5-55: WRITE (Sequential Access) Input Fields

Block Field	Description
RAB BKT	Virtual block number (VBN)
RAB ISI	Internal stream identifier
RAB RBF	Record buffer address
RAB RSZ	Record size (bytes)

Table 5-56: WRITE (Sequential Access) Output Fields

Block Field	Description
RAB RFA	Virtual block number (2 words)
RAB STS	Completion status code
RAB STV	Completion status value

## 5.29 \$WRITE MACRO (VBN ACCESS)

The \$WRITE macro calls the WRITE operation routine to write blocks to a file. The target of a VBN-access WRITE operation is the writable block (and, for a multiblock WRITE operation, following blocks).

### FORMAT

The format for the \$WRITE is:

```
$WRITE rabaddr[, [erraddr][, sucaddr]]
```

where rabaddr is the address of the RAB for the operation; erraddr is the address of the error handler for the operation; and sucaddr is the address of the success handler for the operation.

### CONTROL BLOCKS

You must supply a RAB for the WRITE operation.

### OPTIONS

#### Internal Stream Identifier

The WRITE operation reads the internal stream identifier from the 1-word ISI field of the RAB.

#### Block Identification

Specify the virtual block number of the first block to be written in the 2-word BKT field of the RAB.

#### Record Buffer

Specify the address of the record buffer in the 1-word RBF field of the RAB, and specify the size (in bytes) of the record buffer in the 1-word RSZ field of the RAB. You must specify a record buffer for the WRITE operation; the WRITE operation transfers data from this buffer to the file.

The WRITE operation normally updates the logical end-of-file marker, when appropriate. For sequential files with undefined (UDF) record format, however, the WRITE operation updates the logical end-of-file marker only if no write-sharing has been specified in the 1-byte SHR field of the FAB.

### STREAM CONTEXT

The readable-block context after a WRITE operation is the block following the last-written block; the writable-block context after a WRITE operation is the block following the last-written block.

OPERATION MACRO DESCRIPTIONS  
\$WRITE MACRO (VBN ACCESS)

RETURNED VALUES

Record File Address (RFA)

The WRITE operation returns the virtual block number of the first-written block in the first two words of the 3-word RFA field of the RAB (it clears the third word).

Completion Status and Value

The WRITE operation returns completion status in the 1-word STS field of the RAB and returns a completion value in the 1-word STV field of the RAB. Appendix A lists completion status symbols and values.

CHECKLISTS

Table 5-57 lists control block fields that are input to the WRITE operation. Table 5-58 lists control block fields that are output by the WRITE operation.

Table 5-57: WRITE (VBN Access) Input Fields

Block Field	Description
RAB BKT	Virtual block number (VBN)
RAB ISI	Internal stream identifier

Block Field	Description
RAB RFA	Virtual block number (2 words)
RAB STS	Completion status code
RAB STV	Completion status value

## CHAPTER 6

### CONTROL BLOCK FIELDS

Each major section of this chapter describes an RMS-11 control block, and includes:

- Block summary table

A table summarizes the entire control block. The table shows the offset, offset symbol, field size, and a brief description of each field in the block; for each mask or code for a field, the table shows the value, symbol, and a brief description of the mask or code.

- Field summaries

Each subsection following the block summary table is a description of one field in the block. A field that has masks that are very different in purpose (such as the FOP field in the FAB) is described as a number of separate "fields" (such as FOP FB\$FID, FOP FB\$RWO, and so forth).

The description of each field includes the following:

**USE:** a summary of the purpose of the field

**SIZE:** the size of the field

**INIT:** the format of the field-initialization macro (if any)

**ACCESS:** the formats of field-access macros to access the field

**MASKS or CODES:** (if any) each mask or code symbol and a brief description

**INPUT:** the operations that read values from the field, and the meanings of those values

**OUTPUT:** the operations that store values in the field, and the meanings of those values

Fields described as "Reserved" and undefined bits in masks should (and in some cases must) be 0.

CONTROL BLOCK FIELDS  
ALL BLOCK SUMMARY

6.1 ALL BLOCK SUMMARY

This section summarizes the ALL block and its fields. Table 6-1 summarizes the entire block, giving the offset, offset symbol, size, and a brief description for each field; for a field that has mask or code symbols, the table also gives the value, symbol, and a brief description for each mask or code.

Table 6-1: ALL Block Summary

Offset	Offset Symbol	Field Size	Description
000	O\$COD	1 byte	ALL block identifier code 000004 XB\$ALL ALL block identifier
001	O\$BLN	1 byte	ALL block length (bytes) 000034 XB\$LAL ALL block length (bytes)
002	O\$NXT	1 word	Next XAB address
004	O\$AID	1 byte	Area number
005	O\$BKZ	1 byte	Area bucket size (blocks)
006	O\$VOL	1 word	Reserved
010	O\$ALN	1 byte	Area alignment mask 000002 XB\$LBN Cluster alignment

<b>OUTPUT</b>	DISPLAY Area default extension size (blocks) OPEN Area default extension size (blocks)

6.1.9 LOC Field in ALL Block

**USE**            Contains the location of the area described by the ALL  
                  block.  
  
                  The value in the LOC field is a cluster number.

**INIT**            X\$LOC number

**SIZE**            2 words

**ACCESS**         \$FETCH dst,LOC,reg         ;LOC field to 2-word dst  
                  \$STORE src,LOC,reg         ;2-word src to LOC field  
                  \$FETCH dst,LOCn,reg         ;LOC word n to 1-word dst  
                  \$STORE src,LOCn,reg         ;1-word src to LOC word n  
                  \$COMPARE src,LOCn,reg         ;1-word src with LOC word n

**INPUT**         CREATE         Initial area location request

**CONTROL BLOCK FIELDS**  
**ALL BLOCK SUMMARY**

**6.1.10 NXT Field in ALL Block**

**USE**            Contains the address of the next XAB (ALL, DAT, KEY, PRO, or SUM block) in a chain of XABs.

**INIT**            X\$NXT address

**SIZE**            1 word

**ACCESS**        \$FETCH dst,NXT,reg        ;NXT field to 1-word dst  
                 \$STORE src,NXT,reg        ;1-word src to NXT field  
                 \$COMPARE src,NXT,reg        ;1-word src with NXT field

**INPUT**        CLOSE            Next XAB address  
                 CREATE            Next XAB address  
                 DISPLAY          Next XAB address  
                 ERASE            Next XAB address  
                 EXTEND          Next XAB address  
                 OPEN             Next XAB address  
                 PARSE            Next XAB address  
                 RENAME          Next XAB address  
                 SEARCH         Next XAB address

6.2 DAT BLOCK SUMMARY

This section summarizes the DAT block and its fields. Table 6-2 summarizes the entire block, giving the offset, offset symbol, size, and a brief description for each field; for a field that has mask or code symbols, the table also gives the value, symbol, and a brief description for each mask or code.

Table 6-2: DAT Block Summary

Offset	Offset Symbol	Field Size	Description
000	O\$COD	1 byte	DAT block identifier code 000003 XB\$DAT DAT block identifier
001	O\$BLN	1 byte	DAT block length (bytes) 000046 XB\$DTL DAT block length (bytes)
002	O\$NXT	1 word	Next XAB address
004	O\$RVN	1 word	Reserved
006	O\$RDT	4 words	File revision date
016	O\$CDT	4 words	File creation date
026	O\$EDT	4 words	Reserved
036	O\$BDT	4 words	Reserved

**CONTROL BLOCK FIELDS**  
**DAT BLOCK SUMMARY**

**6.2.1 BLN Field in DAT Block (XB\$DTL Code)**

<b>USE</b>	Contains the length of the DAT block.
<b>INIT</b>	None
<b>SIZE</b>	1 byte
<b>ACCESS</b>	\$FETCH dst,BLN,reg ;BLN field to 1-byte dst \$COMPARE src,BLN,reg ;1-byte src with BLN field

6.2.2 CDT Field in DAT Block

**USE**            Contains the binary creation date for the file. The time value is a binary number in 100-nanosecond units offset from the system base date and time, which is 00:00 o'clock, November 17, 1858 (the Smithsonian base date and time for the astronomical calendar).

**INIT**            None

**SIZE**            4 words

**ACCESS**        \$FETCH dst,CDT,reg        ;CDT field to 4-word dst

**OUTPUT**        OPEN            File creation date

**CONTROL BLOCK FIELDS**  
**DAT BLOCK SUMMARY**

**6.2.3 COD Field in DAT Block (XB\$DAT Code)**

<b>USE</b>	Contains the identifier for the DAT block.	
<b>INIT</b>	None	
<b>SIZE</b>	1 byte	
<b>ACCESS</b>	\$FETCH dst,COD,reg	;COD field to 1-byte dst
	\$COMPARE src,COD,reg	;1-byte src with COD field

6.2.4 NXT Field in DAT Block

<b>USE</b>	Contains the address of the next XAB (ALL, DAT, KEY, PRO, or SUM block) in a chain of XABs.	
<b>INIT</b>	X\$NXT address	
<b>SIZE</b>	1 word	
<b>ACCESS</b>	\$FETCH dst,NXT,reg	;NXT field to 1-word dst
	\$STORE src,NXT,reg	;1-word src to NXT field
	\$COMPARE src,NXT,reg	;1-word src with NXT field
<b>INPUT</b>	CLOSE	Next XAB address
	CREATE	Next XAB address
	DISPLAY	Next XAB address
	ERASE	Next XAB address
	EXTEND	Next XAB address
	OPEN	Next XAB address
	PARSE	Next XAB address
	RENAME	Next XAB address
	SEARCH	Next XAB address

**CONTROL BLOCK FIELDS  
DAT BLOCK SUMMARY**

**6.2.5 RDT Field in DAT Block**

**USE**            Contains the binary revision date for the file. The time value is a binary number in 100-nanosecond units offset from the system base date and time, which is 00:00 o'clock, November 17, 1858 (the Smithsonian base date and time for the astronomical calendar).

**INIT**            None

**SIZE**            4 words

**ACCESS**        \$FETCH dst,RDT,reg        ;RDT field to 4-word dst

**OUTPUT**        OPEN            File revision date

6.3 FAB SUMMARY

This section summarizes the FAB and its fields. Table 6-3 summarizes the entire block, giving the offset, offset symbol, size, and a brief description for each field; for a field that has mask or code symbols, the table also gives the value, symbol, and a brief description for each mask or code.

Table 6-3: FAB Summary

Offset	Offset Symbol	Field Size	Description
000	O\$BID	1 byte	FAB identifier 000003 FB\$BID FAB identification code
001	O\$BLN	1 byte	FAB length (bytes) 000120 FB\$BLN FAB length (bytes)
002	O\$CTX	1 word	User context
004	O\$IFI	1 word	Internal file identifier
006	O\$STS	1 word	Completion status code
010	O\$STV	1 word	Completion status value
012	O\$ALQ	2 words	File allocation size (blocks)
016	O\$DEQ	1 word	File default extension size (blocks)
020	O\$FAC	1 byte	Requested access mask 000001 FB\$PUT Request put access 000002 FB\$GET Request find/get access 000004 FB\$DEL Request find/get/delete access 000010 FB\$UPD Request find/get/update access 000020 FB\$TRN Request find/get/truncate access 000041 FB\$WRT Request block write access 000042 FB\$REA Request block read access
021	O\$SHR	1 byte	Shared access mask 000002 FB\$GET Share find/get access 000015 FB\$WRI Share find/get/put/update/delete access 000100 FB\$NIL No access sharing

(Continued on next page)

Table 6-3 (Cont.): FAB Summary

Offset	Offset Symbol	Field Size	Description
022	O\$FOP	1 word	File processing option mask
			000001 FB\$RWO Rewind magtape before operation
			000002 FB\$RWC Rewind magtape after closing file
			000010 FB\$POS Position magtape after last-closed file
			000020 FB\$DLK No file locking on abnormal close
			000200 FB\$CTG Contiguous file
			000400 FB\$SUP Supersede existing file
			001000 FB\$NEF No end-of-file magtape positioning
			002000 FB\$TMP Temporary file
			004000 FB\$MKD Mark file for deletion
			006000 FB\$TMD Temporary file, mark for deletion
			010000 FB\$FID Use information in NAM block

			000002 FB\$VAR Variable-length record format
			000003 FB\$VFC VFC record format
			000004 FB\$STM Stream record format

(Continued on next page)

Table 6-3 (Cont.): FAB Summary

Offset	Offset Symbol	Field Size	Description
030	O\$XAB	1 word	XAB address
032	O\$BPA	1 word	Private buffer pool address
034	O\$BPS	1 word	Private buffer pool size (bytes)
036	O\$MRS	1 word	Maximum record size (bytes)
040	O\$MRN	2 words	Maximum record number
044	O\$LRL	1 word	Longest record length
046	O\$NAM	1 word	NAM block address
050	O\$FNA	1 word	File string address
052	O\$DNA	1 word	Default string address
054	O\$FNS	1 byte	File string size (bytes)
055	O\$DNS	1 byte	Default string size (bytes)
056	O\$BLS	1 word	Magtape block size (characters)
060	O\$FSZ	1 byte	Fixed control area size for VFC records (bytes)
061	O\$BKS	1 byte	File bucket size (blocks)
062	O\$DEV	1 byte	Device characteristic mask
			000001 FB\$REC Record-oriented device
			000002 FB\$CCL Carriage-control device
			000004 FB\$TRM Terminal device
			000010 FB\$MDI Multidirectory device
			000020 FB\$SDI Single-directory device
			000040 FB\$SQD Sequential device
063	O\$LCH	1 byte	Logical channel number

**CONTROL BLOCK FIELDS  
FAB SUMMARY**

**6.3.1 ALQ Field in FAB**

<b>USE</b>	Contains the allocation size for the file.
<b>INIT</b>	F\$ALQ number
<b>SIZE</b>	2 words
<b>ACCESS</b>	\$FETCH dst,ALQ,reg ;ALQ field to 2-word dst \$STORE src,ALQ,reg ;2-word src to ALQ field \$FETCH dst,ALQn,reg ;ALQ word n to 1-word dst \$STORE src,ALQn,reg ;1-word src to ALQ word n \$COMPARE src,ALQn,reg ;1-word src with ALQ word n
<b>INPUT</b>	CREATE Initial file allocation request size (blocks) EXTEND File allocation extension request size (blocks)
<b>OUTPUT</b>	CREATE Initial file allocation size (blocks) EXTEND File allocation extension actual size (blocks) OPEN Current file allocation (blocks)

6.3.2 BID Field in FAB (FB\$BID Code)

USE	Contains the identifier for the FAB.
INIT	None
SIZE	1 byte
ACCESS	\$FETCH dst,BID,reg ;BID field to 1-byte dst \$COMPARE src,BID,reg ;1-byte src with BID field

**CONTROL BLOCK FIELDS  
FAB SUMMARY**

**6.3.3 BKS Field in FAB**

<b>USE</b>	Contains the bucket size for the file.
<b>INIT</b>	F\$BKS number
<b>SIZE</b>	1 byte
<b>ACCESS</b>	\$FETCH dst,BKS,reg ;BKS field to 1-byte dst \$STORE src,BKS,reg ;1-byte src to BKS field \$COMPARE src,BKS,reg ;1-byte src with BKS field
<b>INPUT</b>	CREATE File bucket size (blocks)
<b>OUTPUT</b>	OPEN File bucket size (blocks)

6.3.4 BLN Field in FAB (FB\$BLN Code)

USE	Contains the length of the FAB.	
INIT	None	
SIZE	1 byte	
ACCESS	\$FETCH dst,BLN,reg	;BLN field to 1-byte dst
	\$COMPARE src,BLN,reg	;1-byte src with BLN field

**CONTROL BLOCK FIELDS  
FAB SUMMARY**

**6.3.5 BLS Field in FAB**

<b>USE</b>	Contains the magtape block size for the file.
<b>INIT</b>	F\$BLS number
<b>SIZE</b>	1 word
<b>ACCESS</b>	\$FETCH dst,BLS,reg ;BLS field to 1-word dst \$STORE src,BLS,reg ;1-word src to BLS field \$COMPARE src,BLS,reg ;1-word src with BLS field
<b>INPUT</b>	CREATE Magtape block size (characters)
<b>OUTPUT</b>	OPEN Magtape block size (characters)

6.3.6 BPA Field in FAB

<b>USE</b>	Contains the address of the private buffer pool for the operation.	
<b>INIT</b>	F\$BPA address	
<b>SIZE</b>	1 word	
<b>ACCESS</b>	\$FETCH dst,BPA,reg	;BPA field to 1-word dst
	\$STORE src,BPA,reg	;1-word src to BPA field
	\$COMPARE src,BPA,reg	;1-word src with BPA field
<b>INPUT</b>	CREATE	Private buffer pool address
	ERASE	Private buffer pool address
	OPEN	Private buffer pool address
	PARSE	Private buffer pool address
	RENAME	Private buffer pool address
	SEARCH	Private buffer pool address
<b>OUTPUT</b>	CLOSE	Private buffer pool address

**CONTROL BLOCK FIELDS  
FAB SUMMARY**

**6.3.7 BPS Field in FAB**

<b>USE</b>	Contains the size of the private buffer pool for the operation.
<b>INIT</b>	F\$BPS number
<b>SIZE</b>	1 word
<b>ACCESS</b>	\$FETCH dst,BPS,reg ;BPS field to 1-word dst \$STORE src,BPS,reg ;1-word src to BPS field \$COMPARE src,BPS,reg ;1-word src with BPS field
<b>INPUT</b>	CREATE Private buffer pool size (bytes) ERASE Private buffer pool size (bytes) OPEN Private buffer pool size (bytes) PARSE Private buffer pool size (bytes) RENAME Private buffer pool size (bytes) SEARCH Private buffer pool size (bytes)
<b>OUTPUT</b>	CLOSE Private buffer pool size (bytes)

6.3.8 CTX Field in FAB

<b>USE</b>	Contains any information you may want to associate with the file at run time.
<b>INIT</b>	F\$CTX number
<b>SIZE</b>	1 word
<b>ACCESS</b>	\$FETCH dst,CTX,reg ;CTX field to 1-word dst \$STORE src,CTX,reg ;1-word src to CTX field \$COMPARE src,CTX,reg ;1-word src with CTX field

**CONTROL BLOCK FIELDS  
FAB SUMMARY**

**6.3.9 DEQ Field in FAB**

<b>USE</b>	Contains the default extension size for the file.
<b>INIT</b>	F\$DEQ number
<b>SIZE</b>	1 word
<b>ACCESS</b>	\$FETCH dst,DEQ,reg ;DEQ field to 1-word dst \$STORE src,DEQ,reg ;1-word src to DEQ field \$COMPARE src,DEQ,reg ;1-word src with DEQ field
<b>INPUT</b>	CREATE Permanent file default extension size (blocks) OPEN While-open file default extension size (blocks)
<b>OUTPUT</b>	OPEN Current file default extension size (blocks)

6.3.10 DEV Field in FAB

<b>USE</b>	Indicates device characteristics for the file.	
<b>INIT</b>	None	
<b>SIZE</b>	1 byte	
<b>ACCESS</b>	\$TESTBITS mask,DEV,reg ;Test mask bits in DEV field \$FETCH dst,DEV,reg ;DEV field to 1-byte dst \$COMPARE src,DEV,reg ;1-byte src with DEV field	
<b>MASKS</b>	FB\$CCL	Carriage-control device
	FB\$MDI	Multidirectory device
	FB\$REC	Record-oriented device
	FB\$SDI	Single-directory device
	FB\$SQD	Sequential device
	FB\$TRM	Terminal device
<b>OUTPUT</b>	CREATE	Device characteristic mask
	ERASE	Device characteristic mask
	OPEN	Device characteristic mask
	PARSE	Device characteristic mask
	RENAME	Device characteristic mask
	SEARCH	Device characteristic mask

**CONTROL BLOCK FIELDS  
FAB SUMMARY**

**6.3.11 DNA Field in FAB**

<b>USE</b>	Contains the address of the default string for the operation.
<b>INIT</b>	F\$DNA address
<b>SIZE</b>	1 word
<b>ACCESS</b>	\$FETCH dst,DNA,reg ;DNA field to 1-word dst \$STORE src,DNA,reg ;1-word src to DNA field \$COMPARE src,DNA,reg ;1-word src with DNA field
<b>INPUT</b>	CREATE Default string address ERASE Default string address OPEN Default string address PARSE Default string address RENAME Default string address

6.3.12 DNS Field in FAB

**USE**            Contains the size of the default string for the operation.

**INIT**            F\$DNS number

**SIZE**            1 byte

**ACCESS**        \$FETCH dst,DNS,reg        ;DNS field to 1-byte dst  
                 \$STORE src,DNS,reg        ;1-byte src to DNS field  
                 \$COMPARE src,DNS,reg        ;1-byte src with DNS field

**INPUT**        CREATE            Default string size (bytes)  
                 ERASE            Default string size (bytes)  
                 OPEN            Default string size (bytes)  
                 PARSE            Default string size (bytes)  
                 RENAME          Default string size (bytes)

**CONTROL BLOCK FIELDS  
FAB SUMMARY**

**6.3.13 FAC Field in FAB**

**USE** Indicates the requested access for the file.

**INIT** F\$FAC mask

**SIZE** 1 byte

**ACCESS** \$SET mask,FAC,reg ;Mask bits on in FAC field  
\$OFF mask,FAC,reg ;Mask bits off in FAC field  
\$TESTBITS mask,FAC,reg ;Test mask bits in FAC field  
\$FETCH dst,FAC,reg ;FAC field to 1-byte dst

**INPUT** CREATE Temporary file

6.3.26 FSZ Field in FAB

<b>USE</b>	Contains the size of the fixed control area for VFC records.		
<b>INIT</b>	F\$FSZ number		
<b>SIZE</b>	1 byte		
<b>ACCESS</b>	\$FETCH dst,FSZ,reg	;FSZ field to 1-byte dst	
	\$STORE src,FSZ,reg	;1-byte src to FSZ field	
	\$COMPARE src,FSZ,reg	;1-byte src with FSZ field	
<b>INPUT</b>	CREATE	Fixed control area size for VFC records (bytes)	
<b>OUTPUT</b>	OPEN	Fixed control area size for VFC records (bytes)	

**CONTROL BLOCK FIELDS  
FAB SUMMARY**

**6.3.27 IFI Field in FAB**

<b>USE</b>	Contains the internal file identifier for the file.	
<b>INIT</b>	None	
<b>SIZE</b>	1 word	
<b>ACCESS</b>	\$FETCH dst,IFI,reg	;IFI field to 1-word dst
	\$COMPARE src,IFI,reg	;1-word src with IFI field
<b>INPUT</b>	CLOSE	Internal file identifier
	CONNECT	Internal file identifier
	DISPLAY	Internal file identifier
	EXTEND	Internal file identifier
<b>OUTPUT</b>	CLOSE	Internal file identifier
	CREATE	Internal file identifier
	OPEN	Internal file identifier

6.3.28 LCH Field in FAB

**USE**            Contains the logical channel number for the operation.

**INIT**            F\$LCH number

**SIZE**            1 byte

**ACCESS**        \$FETCH dst,LCH,reg        ;LCH field to 1-byte dst  
                  \$STORE src,LCH,reg        ;1-byte src to LCH field  
                  \$COMPARE src,LCH,reg       ;1-byte src with LCH field

**INPUT**        CREATE            Logical channel number  
                  ERASE            Logical channel number  
                  OPEN             Logical channel number  
                  PARSE           Logical channel number  
                  RENAME          Logical channel number  
                  SEARCH         Logical channel number

**CONTROL BLOCK FIELDS  
FAB SUMMARY**

**6.3.29 LRL Field in FAB**

<b>USE</b>	Contains the length of the longest record in a sequential file.
<b>INIT</b>	None
<b>SIZE</b>	1 word
<b>ACCESS</b>	\$FETCH dst,LRL,reg ;LRL field to 1-word dst \$COMPARE src,LRL,reg ;1-word src with LRL field
<b>INPUT</b>	CREATE Longest record length (block access to sequential files only)
<b>OUTPUT</b>	OPEN Longest record length

6.3.30 MRN Field in FAB

**USE**            Contains the maximum record number allowed in a relative file.

**INIT**            F\$MRN number

**SIZE**            2 words

**ACCESS**        \$FETCH dst,MRN,reg        ;MRN field to 2-word dst  
                  \$STORE src,MRN,reg        ;2-word src to MRN field  
                  \$FETCH dst,MRNn,reg       ;MRN word n to 1-word dst  
                  \$STORE src,MRNn,reg       ;1-word src to MRN word n  
                  \$COMPARE src,MRNn,reg   ;1-word src with MRN word n

**INPUT**        CREATE            Maximum record number

**OUTPUT**       OPEN              Maximum record number

**CONTROL BLOCK FIELDS  
FAB SUMMARY**

**6.3.31 MRS Field in FAB**

<b>USE</b>	Contains the record size for fixed-length records or maximum record size for other format records for the file.
<b>INIT</b>	F\$MRS number
<b>SIZE</b>	1 word
<b>ACCESS</b>	\$FETCH dst,MRS,reg ;MRS field to 1-word dst \$STORE src,MRS,reg ;1-word src to MRS field \$COMPARE src,MRS,reg ;1-word src with MRS field
<b>INPUT</b>	CREATE Maximum record size (bytes)
<b>OUTPUT</b>	OPEN Maximum record size (bytes)

6.3.32 NAM Field in FAB

<b>USE</b>	Contains the address of the NAM block for the operation.	
<b>INIT</b>	F\$NAM address	
<b>SIZE</b>	1 word	
<b>ACCESS</b>	\$FETCH dst,NAM,reg	;NAM field to 1-word dst
	\$STORE src,NAM,reg	;1-word src to NAM field
	\$COMPARE src,NAM,reg	;1-word src with NAM field
<b>INPUT</b>	CREATE	NAM block address
	ERASE	NAM block address
	OPEN	NAM block address
	PARSE	NAM block address
	RENAME	NAM block address
	SEARCH	NAM block address

**CONTROL BLOCK FIELDS  
FAB SUMMARY**

**6.3.33 ORG Field in FAB**

**USE**            Contains the file organization code.

**INIT**            F\$ORG code

**SIZE**            1 byte

**ACCESS**        \$FETCH dst,ORG,reg        ;ORG field to 1-byte dst  
                 \$STORE src,ORG,reg        ;1-byte src to ORG field  
                 \$COMPARE src,ORG,reg       ;1-byte src with ORG field

**CODES**        FB\$IDX    Indexed file organization  
                 FB\$REL    Relative file organization  
                 FB\$SEQ    Sequential file organization

**INPUT**        CREATE        File organization code

**OUTPUT**        OPEN            File organization code

6.3.34 RAT Field in FAB

**USE** Indicates the record-output characteristic for the file.  
(The RAT field also contains the record-blocking characteristic, which is described in the next section.)

**INIT** F\$RAT mask

**SIZE** 1 byte

**ACCESS** \$SET mask,RAT,reg ;Mask bits on in RAT field  
\$OFF mask,RAT,reg ;Mask bits off in RAT field  
\$TESTBITS mask,RAT,reg ;Test mask bits in RAT field  
\$FETCH dst,RAT,reg ;RAT field to 1-byte dst  
\$STORE src,RAT,reg ;1-byte src to RAT field  
\$COMPARE src,RAT,reg ;1-byte src with RAT field

**MASKS** FB\$CR Add CRLF to print record (LF-record-CR)  
FB\$FTN FORTRAN-style carriage-control character in record  
FB\$PRN VFC print record handling

**INPUT** CREATE Record handling mask

**OUTPUT** OPEN Record handling mask

**CONTROL BLOCK FIELDS  
FAB SUMMARY**

**6.3.35 RAT Field in FAB (FB\$BLK Mask)**

**USE**            Indicates whether the file has blocked records. (The RAT field also contains the record-output characteristic, which is described in the previous section.)

**INIT**            F\$RAT mask

**SIZE**            1 byte

**ACCESS**        \$SET mask,RAT,reg        ;Mask bits on in RAT field  
                 \$OFF mask,RAT,reg        ;Mask bits off in RAT field  
                 \$TESTBITS mask,RAT,reg ;Test mask bits in RAT field  
                 \$FETCH dst,RAT,reg       ;RAT field to 1-byte dst  
                 \$STORE src,RAT,reg       ;1-byte src to RAT field  
                 \$COMPARE src,RAT,reg     ;1-byte src with RAT field

**INPUT**         CREATE        Blocked records

**OUTPUT**        OPEN         Blocked records

6.3.36 RFM Field in FAB

<b>USE</b>	Contains the record format code for the file.	
<b>INIT</b>	F\$RFM code	
<b>SIZE</b>	1 byte	
<b>ACCESS</b>	\$FETCH dst,RFM,reg	;RFM field to 1-byte dst
	\$STORE src,RFM,reg	;1-byte src to RFM field
	\$COMPARE src,RFM,reg	;1-byte src with RFM field
<b>CODES</b>	FB\$FIX	Fixed-length record format
	FB\$STM	Stream record format
	FB\$UDF	Undefined record format
	FB\$VAR	Variable-length record format
	FB\$VFC	VFC record format
<b>INPUT</b>	CREATE	Record format code
<b>OUTPUT</b>	OPEN	Record format code

**CONTROL BLOCK FIELDS  
FAB SUMMARY**

**6.3.37 RTV Field in FAB**

<b>USE</b>	Contains the cluster size for the file.	
<b>INIT</b>	F\$RTV number	
<b>SIZE</b>	1 byte	
<b>ACCESS</b>	\$FETCH dst,RTV,reg	;RTV field to 1-byte dst
	\$STORE src,RTV,reg	;1-byte src to RTV field
	\$COMPARE src,RTV,reg	;1-byte src with RTV field
<b>INPUT</b>	CREATE	Cluster size (blocks)
<b>OUTPUT</b>	OPEN	Cluster size (blocks)

6.3.38 SHR Field in FAB

**USE** Indicates requested access sharing for the file.

**INIT** F\$SHR mask

**SIZE** 1 byte

**ACCESS** \$SET mask,SHR,reg ;Mask bits on in SHR field  
 \$OFF mask,SHR,reg ;Mask bits off in SHR field  
 \$TESTBITS mask,SHR,reg ;Test mask bits in SHR field  
 \$FETCH dst,SHR,reg ;SHR field to 1-byte dst  
 \$STORE src,SHR,reg ;1-byte src to SHR field  
 \$COMPARE src,SHR,reg ;1-byte src with SHR field

**MASKS** FB\$GET Share find/get access  
 FB\$NIL No access sharing  
 FB\$WRI Share find/get/put/update/delete access

**INPUT** CREATE Shared access mask  
 OPEN Shared access mask

**CONTROL BLOCK FIELDS  
FAB SUMMARY**

**6.3.39 STS Field in FAB**

<b>USE</b>	Contains the completion status code for the operation.	
<b>INIT</b>	None	
<b>SIZE</b>	1 word	
<b>ACCESS</b>	\$FETCH dst,STS,reg	;STS field to 1-word dst
	\$COMPARE src,STS,reg	;1-word src with STS field
<b>OUTPUT</b>	CLOSE	Completion status code
	CREATE	Completion status code
	DISPLAY	Completion status code
	ERASE	Completion status code
	EXTEND	Completion status code
	OPEN	Completion status code
	PARSE	Completion status code
	RENAME	Completion status code
	SEARCH	Completion status code

6.3.40 STV Field in FAB

<b>USE</b>	Contains the completion status value for the operation.	
<b>INIT</b>	None	
<b>SIZE</b>	1 word	
<b>ACCESS</b>	\$FETCH dst,STV,reg	;STV field to 1-word dst
	\$COMPARE src,STV,reg	;1-word src with STV field
<b>OUTPUT</b>	CLOSE	Completion status value
	CREATE	Completion status value
	DISPLAY	Completion status value
	ERASE	Completion status value
	EXTEND	Completion status value
	OPEN	Completion status value
	PARSE	Completion status value
	RENAME	Completion status value
	SEARCH	Completion status value

**CONTROL BLOCK FIELDS  
FAB SUMMARY**

**6.3.41 XAB Field in FAB**

<b>USE</b>	Contains the address of the first XAB (ALL, DAT, KEY, PRO, or SUM block) in a chain of XABs.	
<b>INIT</b>	F\$XAB address	
<b>SIZE</b>	1 word	
<b>ACCESS</b>	\$FETCH dst,XAB,reg	;XAB field to 1-word dst
	\$STORE src,XAB,reg	;1-word src to XAB field
	\$COMPARE src,XAB,reg	;1-word src with XAB field
<b>INPUT</b>	CLOSE	XAB address
	CREATE	XAB address
	DISPLAY	XAB address
	EXTEND	XAB address
	OPEN	XAB address

6.4 KEY BLOCK SUMMARY

This section summarizes the KEY block and its fields. Table 6-4 summarizes the entire block, giving the offset, offset symbol, size, and a brief description for each field; for a field that has mask or code symbols, the table also gives the value, symbol, and a brief description for each mask or code.

Table 6-4: KEY Block Summary

Offset	Offset Symbol	Field Size	Description
000	O\$COD	1 byte	KEY block identifier code 000001 XB\$KEY KEY block identifier
001	O\$BLN	1 byte	KEY block length (bytes) 000070 XB\$KYL KEY block length (bytes)
002	O\$NXT	1 word	Next XAB address
004	O\$REF	1 byte	Index reference number
005	O\$LVL	1 byte	Number of index levels (not including data level)
006	O\$IFL	1 word	Index bucket fill factor
010	O\$DFL	1 word	Data bucket fill factor
012	O\$NUL	1 byte	Null key character
013	O\$IAN	1 byte	Higher level index area number
014	O\$LAN	1 byte	Lowest index level area number
015	O\$DAN	1 byte	Data area number
016	O\$FLG	1 byte	Index option mask 000001 XB\$DUP Duplicate record keys allowed 000002 XB\$CHG Record key changes allowed on update 000020 XB\$INI No entries yet made in index 000004 XB\$NUL Null record keys not indexed
017	O\$DTP	1 byte	Key data type code 000000 XB\$STG String 000001 XB\$IN2 15-bit signed integer 000002 XB\$BN2 16-bit unsigned integer 000003 XB\$IN4 31-bit signed integer 000004 XB\$BN4 32-bit unsigned integer 000005 XB\$PAC Packed decimal number

(Continued on next page)

CONTROL BLOCK FIELDS  
KEY BLOCK SUMMARY

Table 6-4 (Cont.): KEY Block Summary

Offset	Offset Symbol	Field Size	Description
020	O\$KNM	1 word	Key name buffer address
022	O\$POS	8 words	Key segment positions
022	O\$POS0	1 word	Key segment 0 position
024	O\$POS1	1 word	Key segment 1 position
026	O\$POS2	1 word	Key segment 2 position
030	O\$POS3	1 word	Key segment 3 position
032	O\$POS4	1 word	Key segment 4 position
034	O\$POS5	1 word	Key segment 5 position
036	O\$POS6	1 word	Key segment 6 position
040	O\$POS7	1 word	Key segment 7 position
042	O\$SIZ	8 bytes	Key segment sizes (bytes)
042	O\$SIZ0	1 byte	Key segment 0 size (bytes)
043	O\$SIZ1	1 byte	Key segment 1 size (bytes)
044	O\$SIZ2	1 byte	Key segment 2 size (bytes)
045	O\$SIZ3	1 byte	Key segment 3 size (bytes)
046	O\$SIZ4	1 byte	Key segment 4 size (bytes)
047	O\$SIZ5	1 byte	Key segment 5 size (bytes)
050	O\$SIZ6	1 byte	Key segment 6 size (bytes)
051	O\$SIZ7	1 byte	Key segment 7 size (bytes)
052	O\$RVB	2 words	Root index bucket virtual block number
056	O\$DVB	2 words	First data bucket virtual block number
062	O\$IBS	1 byte	Index area bucket size (blocks)
063	O\$DBS	1 byte	Data area bucket size (blocks)
064	O\$NSG	1 byte	Key segment count
065	O\$TKS	1 byte	Total key size (sum of key segment sizes) (bytes)
066	O\$MRL	1 word	Minimum length of record containing key (bytes)

6.4.1 BLN Field in KEY Block (XB\$KYL Code)

<b>USE</b>	Contains the length of the KEY block.	
<b>INIT</b>	None	
<b>SIZE</b>	1 byte	
<b>ACCESS</b>	\$FETCH dst,BLN,reg	;BLN field to 1-byte dst
	\$COMPARE src,BLN,reg	;1-byte src with BLN field

**CONTROL BLOCK FIELDS  
KEY BLOCK SUMMARY**

**6.4.2 COD Field in KEY Block (XB\$KEY Code)**

<b>USE</b>	Contains the identifier for the KEY block.	
<b>INIT</b>	None	
<b>SIZE</b>	1 byte	
<b>ACCESS</b>	\$FETCH dst,COD,reg	;COD field to 1-byte dst
	\$COMPARE src,COD,reg	;1-byte src with COD field

6.4.3 DAN Field in KEY Block

<b>USE</b>	Contains the area number of the data area for the index described by the KEY block.	
<b>INIT</b>	X\$DAN number	
<b>SIZE</b>	1 byte	
<b>ACCESS</b>	\$FETCH dst,DAN,reg	;DAN field to 1-byte dst
	\$STORE src,DAN,reg	;1-byte src to DAN field
	\$COMPARE src,DAN,reg	;1-byte src with DAN field
<b>INPUT</b>	CREATE	Data area number
<b>OUTPUT</b>	DISPLAY	Data area number
	OPEN	Data area number

**CONTROL BLOCK FIELDS  
KEY BLOCK SUMMARY**

**6.4.4 DBS Field in KEY Block**

<b>USE</b>	Contains the bucket size for the data area for the index described by the KEY block.
<b>INIT</b>	None
<b>SIZE</b>	1 byte
<b>ACCESS</b>	\$FETCH dst,DBS,reg ;DBS field to 1-byte dst \$COMPARE src,DBS,reg ;1-byte src with DBS field
<b>OUTPUT</b>	DISPLAY Data area bucket size (blocks) OPEN Data area bucket size (blocks)

6.4.5 DFL Field in KEY Block

<b>USE</b>	Contains the bucket fill number for the data area for the index described by the KEY block.
<b>INIT</b>	X\$DFL number
<b>SIZE</b>	1 word
<b>ACCESS</b>	\$FETCH dst,DFL,reg ;DFL field to 1-word dst \$STORE src,DFL,reg ;1-word src to DFL field \$COMPARE src,DFL,reg ;1-word src with DFL field
<b>INPUT</b>	CREATE Data bucket fill factor
<b>OUTPUT</b>	DISPLAY Data bucket fill factor OPEN Data bucket fill factor

CONTROL BLOCK FIELDS  
KEY BLOCK SUMMARY

6.4.6 DTP Field in KEY Block

<b>USE</b>	Contains the key data type code for the index described by the KEY block.
<b>INIT</b>	X\$DTP code
<b>SIZE</b>	1 byte
<b>ACCESS</b>	\$FETCH dst,DTP,reg ;DTP field to 1-byte dst \$STORE src,DTP,reg ;1-byte src to DTP field \$COMPARE src,DTP,reg ;1-byte src with DTP field
<b>CODES</b>	XB\$BN2 16-bit unsigned integer XB\$BN4 32-bit unsigned integer XB\$IN2 15-bit signed integer XB\$IN4 31-bit signed integer XB\$PAC Packed decimal number XB\$STG String
<b>INPUT</b>	CREATE Key data type code
<b>OUTPUT</b>	DISPLAY Key data type code OPEN Key data type code

6.4.7 DVB Field in KEY Block

<b>USE</b>	Contains the virtual block number of the first bucket in the data area for the index described by the KEY block.
<b>INIT</b>	None
<b>SIZE</b>	2 words
<b>ACCESS</b>	\$FETCH dst,DVB,reg ;DVB field to 2-word dst
<b>OUTPUT</b>	DISPLAY First data bucket virtual block number OPEN First data bucket virtual block number

**CONTROL BLOCK FIELDS  
KEY BLOCK SUMMARY**

**6.4.8 FLG Field in KEY Block (XB\$CHG Mask)**

**USE** Specifies that a record key (for an alternate index) is allowed to change when the record is updated.

**INIT** X\$FLG mask

**SIZE** 1 byte

**ACCESS** \$SET mask,FLG,reg ;Mask bits on in FLG field  
\$OFF mask,FLG,reg ;Mask bits off in FLG field  
\$TESTBITS mask,FLG,reg ;Test mask bits in FLG field  
\$FETCH dst,FLG,reg ;FLG field to 1-byte dst  
\$STORE src,FLG,reg ;1-byte src to FLG field  
\$COMPARE src,FLG,reg ;1-byte src with FLG field

**INPUT** CREATE Record key changes allowed on update

**OUTPUT** DISPLAY Record key changes allowed on update  
OPEN Record key changes allowed on update

6.4.9 FLG Field in KEY Block (XB\$DUP Mask)

**USE** Indicates that duplicate record keys are allowed for the index described by the KEY block; duplicate record keys are not allowed in the primary index.

**INIT** X\$FLG mask

**SIZE** 1 byte

**ACCESS** \$SET mask,FLG,reg ;Mask bits on in FLG field  
 \$OFF mask,FLG,reg ;Mask bits off in FLG field  
 \$TESTBITS mask,FLG,reg ;Test mask bits in FLG field  
 \$FETCH dst,FLG,reg ;FLG field to 1-byte dst  
 \$STORE src,FLG,reg ;1-byte src to FLG field  
 \$COMPARE src,FLG,reg ;1-byte src with FLG field

**INPUT** CREATE Duplicate record keys allowed

**OUTPUT** DISPLAY Duplicate record keys allowed  
 OPEN Duplicate record keys allowed

**CONTROL BLOCK FIELDS  
KEY BLOCK SUMMARY**

**6.4.10 FLG Field in KEY Block (XB\$NUL Mask)**

<b>USE</b>	Indicates that records containing only null characters are not contained in the index described by the KEY block. (The null character is specified in the NUL field of the KEY block.)	
<b>INIT</b>	X\$FLG mask	
<b>SIZE</b>	1 byte	
<b>ACCESS</b>	\$SET mask,FLG,reg	;Mask bits on in FLG field
	\$OFF mask,FLG,reg	;Mask bits off in FLG field
	\$TESTBITS mask,FLG,reg	;Test mask bits in FLG field
	\$FETCH dst,FLG,reg	;FLG field to 1-byte dst
	\$STORE src,FLG,reg	;1-byte src to FLG field
	\$COMPARE src,FLG,reg	;1-byte src with FLG field
<b>INPUT</b>	CREATE	Null record keys not indexed
<b>OUTPUT</b>	DISPLAY	Null record keys not indexed
	OPEN	Null record keys not indexed

6.4.11 IAN Field in KEY Block

**USE**            Contains the area number of the area containing the higher index levels (all except the lowest level) for the index described by the KEY block.

**INIT**            X\$IAN number

**SIZE**            1 byte

**ACCESS**        \$FETCH dst,IAN,reg        ;IAN field to 1-byte dst  
                 \$STORE src,IAN,reg        ;1-byte src to IAN field  
                 \$COMPARE src,IAN,reg        ;1-byte src with IAN field

**INPUT**        CREATE        Higher level index area number

**OUTPUT**      DISPLAY        Higher level index area number  
                 OPEN            Higher level index area number

**CONTROL BLOCK FIELDS  
KEY BLOCK SUMMARY**

**6.4.12 IBS Field in KEY Block**

<b>USE</b>	Contains the bucket size of the area containing the index described by the KEY block.
<b>INIT</b>	None
<b>SIZE</b>	1 byte
<b>ACCESS</b>	\$FETCH dst,IBS,reg ;IBS field to 1-byte dst \$COMPARE src,IBS,reg ;1-byte src with IBS field
<b>OUTPUT</b>	DISPLAY Index area bucket size (blocks) OPEN Index area bucket size (blocks)

6.4.13 IFL Field in KEY Block

<b>USE</b>	Contains the bucket fill number for the area containing the index described by the KEY block.	
<b>INIT</b>	X\$IFL number	
<b>SIZE</b>	1 word	
<b>ACCESS</b>	\$FETCH dst,IFL,reg	;IFL field to 1-word dst
	\$STORE src,IFL,reg	;1-word src to IFL field
	\$COMPARE src,IFL,reg	;1-word src with IFL field
<b>INPUT</b>	CREATE	Index bucket fill factor
<b>OUTPUT</b>	DISPLAY	Index bucket fill factor
	OPEN	Index bucket fill factor

**CONTROL BLOCK FIELDS  
KEY BLOCK SUMMARY**

**6.4.14 KNM Field in KEY Block**

<b>USE</b>	Contains the address of the 32-byte key name buffer for the index described by the KEY block.
<b>INIT</b>	X\$KNM address
<b>SIZE</b>	1 word
<b>ACCESS</b>	\$FETCH dst,KNM,reg ;KNM field to 1-word dst \$STORE src,KNM,reg ;1-word src to KNM field \$COMPARE src,KNM,reg ;1-word src with KNM field
<b>INPUT</b>	CREATE Key name buffer address DISPLAY Key name buffer address OPEN Key name buffer address

6.4.15 LAN Field in KEY Block

<b>USE</b>	Contains the area number of the area containing the lowest level of the index described by the KEY block.	
<b>INIT</b>	X\$LAN number	
<b>SIZE</b>	1 byte	
<b>ACCESS</b>	\$FETCH dst,LAN,reg	;LAN field to 1-byte dst
	\$STORE src,LAN,reg	;1-byte src to LAN field
	\$COMPARE src,LAN,reg	;1-byte src with LAN field
<b>INPUT</b>	CREATE	Lowest index level area number
<b>OUTPUT</b>	DISPLAY	Lowest index level area number
	OPEN	Lowest index level area number

**CONTROL BLOCK FIELDS  
KEY BLOCK SUMMARY**

**6.4.16 LVL Field in KEY Block**

<b>USE</b>	Contains the number of levels (not including the data level) for the index described by the KEY block.		
<b>INIT</b>	None		
<b>SIZE</b>	1 byte		
<b>ACCESS</b>	\$FETCH dst,LVL,reg		;LVL field to 1-byte dst
	\$COMPARE src,LVL,reg		;1-byte src with LVL field
<b>OUTPUT</b>	<b>DISPLAY</b>	Number of index levels	(not including data level)
	<b>OPEN</b>	Number of index levels	(not including data level)

6.4.17 MRL Field in KEY Block

<b>USE</b>	Contains the length of the smallest record that is long enough to completely contain a record key for the index described by the KEY block.				
<b>INIT</b>	None				
<b>SIZE</b>	1 word				
<b>ACCESS</b>	\$FETCH	dst,MRL,reg	;MRL field to 1-word dst		
	\$COMPARE	src,MRL,reg	;1-word src with MRL field		
<b>OUTPUT</b>	DISPLAY	Minimum length of record containing key (bytes)			
	OPEN	Minimum length of record containing key (bytes)			

**CONTROL BLOCK FIELDS  
KEY BLOCK SUMMARY**

**6.4.18 NSG Field in KEY Block**

<b>USE</b>	Contains the number of key segments in the key for the index described by the KEY block.
<b>INIT</b>	None
<b>SIZE</b>	1 byte
<b>ACCESS</b>	\$FETCH dst,NSG,reg ;NSG field to 1-byte dst \$COMPARE src,NSG,reg ;1-byte src with NSG field
<b>OUTPUT</b>	DISPLAY Key segment count OPEN Key segment count

6.4.19 NUL Field in KEY Block

**USE** Contains the null character for the (alternate) index described by the KEY block. For a string key (XB\$STG in the DTP field of the KEY block), the NUL field contains an ASCII character; for any other key data type, the NUL field is unused (nonstring keys use 0 as the null value when the XB\$NUL mask is set).

**INIT** X\$NUL number

**SIZE** 1 byte

**ACCESS** \$FETCH dst,NUL,reg ;NUL field to 1-byte dst  
 \$STORE src,NUL,reg ;1-byte src to NUL field  
 \$COMPARE src,NUL,reg ;1-byte src with NUL field

**INPUT** CREATE Null key character

**OUTPUT** DISPLAY Null key character  
 OPEN Null key character

CONTROL BLOCK FIELDS  
KEY BLOCK SUMMARY

6.4.20 NXT Field in KEY Block

USE	Contains the address of the next XAB (ALL, DAT, KEY, PRO, or SUM block) in a chain of XABs.	
INIT	X\$NXT address	
SIZE	1 word	
ACCESS	\$FETCH dst,NXT,reg	;NXT field to 1-word dst
	\$STORE src,NXT,reg	;1-word src to NXT field
	\$COMPARE src,NXT,reg	;1-word src with NXT field
INPUT	CLOSE	Next XAB address
	CREATE	Next XAB address
	DISPLAY	Next XAB address
	ERASE	Next XAB address
	EXTEND	Next XAB address
	OPEN	Next XAB address
	PARSE	Next XAB address
	RENAME	Next XAB address
	SEARCH	Next XAB address

6.4.21 POS Field in KEY Block

**USE** Contains the positions of segments for the record keys in the index described by the KEY block. (The first key position is position 0.)

**INIT** X\$POS <number[,number]...>

**SIZE** 8 words

**ACCESS**

\$FETCH dst,POS,reg	;POS field to 8-word dst
\$STORE src,POS,reg	;8-word src to POS field
\$FETCH dst,POSn,reg	;POS word n to 1-word dst
\$STORE src,POSn,reg	;1-word src to POS word n
\$COMPARE src,POSn,reg	;1-word src with POS word n

**INPUT**

CREATE	Key segment positions
--------	-----------------------

**OUTPUT**

DISPLAY	Key segment positions
OPEN	Key segment positions

CONTROL BLOCK FIELDS  
KEY BLOCK SUMMARY

6.4.22 REF Field in KEY Block

<b>USE</b>	Contains the reference number for the index described by the KEY block.
<b>INIT</b>	X\$REF number
<b>SIZE</b>	1 byte
<b>ACCESS</b>	\$FETCH dst,REF,reg ;REF field to 1-byte dst \$STORE src,REF,reg ;1-byte src to REF field \$COMPARE src,REF,reg ;1-byte src with REF field
<b>INPUT</b>	CLOSE Index reference number CREATE Index reference number DISPLAY Index reference number EXTEND Index reference number OPEN Index reference number

6.4.23 RVB Field in KEY Block

<b>USE</b>	Contains the virtual block number of the first block of the root bucket of the index described by the KEY block.
<b>INIT</b>	None
<b>SIZE</b>	2 words
<b>ACCESS</b>	\$FETCH dst,RVB,reg ;RVB field to 2-word dst
<b>OUTPUT</b>	DISPLAY Root index bucket virtual block number OPEN Root index bucket virtual block number

CONTROL BLOCK FIELDS  
KEY BLOCK SUMMARY

6.4.24 SIZ Field in KEY Block

USE            Contains the sizes of segments for the record keys in the  
                 index described by the KEY block.

INIT           X\$SIZ <number[,number]...>

SIZE           8 bytes

ACCESS        \$FETCH dst,SIZ,reg        ;SIZ field to 8-byte dst  
                 \$STORE src,SIZ,reg        ;8-byte src to SIZ field  
                 \$FETCH dst,SIZn,reg       ;SIZ byte n to 1-byte dst  
                 \$STORE src,SIZn,reg       ;1-byte src to SIZ byte n  
                 \$COMPARE src,SIZn,reg     ;1-byte src with SIZ byte n

INPUT        CREATE        Key segment sizes (bytes)

OUTPUT       DISPLAY        Key segment sizes (bytes)  
                 OPEN            Key segment sizes (bytes)

6.4.25 TKS Field in KEY Block

<b>USE</b>	Contains the total key size (sum of the segment sizes) of a record key for the index described by the KEY block.		
<b>INIT</b>	None		
<b>SIZE</b>	1 byte		
<b>ACCESS</b>	\$FETCH dst,TKS,reg		;TKS field to 1-byte dst
	\$COMPARE src,TKS,reg		;1-byte src with TKS field
<b>OUTPUT</b>	DISPLAY	Total key size (sum of key segment sizes)	(bytes)
	OPEN	Total key size (sum of key segment sizes)	(bytes)

CONTROL BLOCK FIELDS  
NAM BLOCK SUMMARY

6.5 NAM BLOCK SUMMARY

This section summarizes the NAM block and its fields. Table 6-5 summarizes the entire block, giving the offset, offset symbol, size, and a brief description for each field; for a field that has mask or code symbols, the table also gives the value, symbol, and a brief description for each mask or code.

Table 6-5: NAM Block Summary

Offset	Offset Symbol	Field Size	Description
000	O\$RLF	1 word	Reserved
002	O\$RSA	1 word	Resultant string buffer address
004	O\$RSS	1 byte	Resultant string buffer size (bytes)
005	O\$RSL	1 byte	Resultant string length (bytes)
006	O\$DVI	2 words	Device identifier
012	O\$WDI	1 word	Wildcard directory context
014	O\$FID	3 words	File identifier
022	O\$DID	3 words	Reserved
030	O\$FNB	1 word	File specification mask
			000001 NB\$VER File version in file string or default string
			000002 NB\$TYP File type in file string or default string
			000004 NB\$NAM File name in file string or default string
			000010 NB\$WVE Wildcard file version in file string or default string
			000020 NB\$WTY Wildcard file type in file string or default string
			000040 NB\$WNA Wildcard file name in file string or default string
			000100 NB\$DIR Directory in file string or default string
			000200 NB\$DEV Device in file string or default string
			000400 NB\$NOD Node in file string or default string
			001000 NB\$WDI Wildcard directory in file string or default string
			002000 NB\$QUO Quoted string in file string or default string
			004000 NB\$WCH Wildcard context established
032	O\$ESA	1 word	Expanded string buffer address
034	O\$ESS	1 byte	Expanded string buffer size (bytes)
035	O\$ESL	1 byte	Expanded string length (bytes)
036	O\$WCC	1 word	Wildcard context

The first word of the NAM block is currently reserved, as noted above, and must contain the value 0. If the NAM block is extended in the future, the first byte will contain an identifier and the second byte will contain the (new) block length.

6.5.1 DVI Field in NAM Block

<b>USE</b>	Contains the device identifier for the target file.	
<b>INIT</b>	None	
<b>SIZE</b>	2 words	
<b>ACCESS</b>	\$FETCH dst,DVI,reg ;DVI field to 2-word dst	
<b>INPUT</b>	CREATE	Device identifier
	ERASE	Device identifier
	OPEN	Device identifier
	RENAME	Device identifier
	SEARCH	Device identifier
<b>OUTPUT</b>	CREATE	Device identifier
	ERASE	Device identifier
	OPEN	Device identifier
	PARSE	Device identifier
	RENAME	Device identifier

**CONTROL BLOCK FIELDS  
NAM BLOCK SUMMARY**

**6.5.2 ESA Field in NAM Block**

<b>USE</b>	Contains the address of the expanded string buffer.
<b>INIT</b>	N\$ESA address
<b>SIZE</b>	1 word
<b>ACCESS</b>	\$FETCH dst,ESA,reg ;ESA field to 1-word dst \$STORE src,ESA,reg ;1-word src to ESA field \$COMPARE src,ESA,reg ;1-word src with ESA field
<b>INPUT</b>	CREATE Expanded string buffer address ERASE Expanded string buffer address OPEN Expanded string buffer address PARSE Expanded string buffer address RENAME Expanded string buffer address SEARCH Expanded string buffer address

6.5.3 ESL Field in NAM Block

<b>USE</b>	Contains the length of the expanded string.	
<b>INIT</b>	None	
<b>SIZE</b>	1 byte	
<b>ACCESS</b>	\$FETCH dst,ESL,reg	;ESL field to 1-byte dst
	\$COMPARE src,ESL,reg	;1-byte src with ESL field
<b>INPUT</b>	SEARCH	Expanded string length (bytes)
<b>OUTPUT</b>	CREATE	Expanded string length (bytes)
	ERASE	Expanded string length (bytes)
	OPEN	Expanded string length (bytes)
	PARSE	Expanded string length (bytes)
	RENAME	Expanded string length (bytes)

**CONTROL BLOCK FIELDS  
NAM BLOCK SUMMARY**

**6.5.4 ESS Field in NAM Block**

<b>USE</b>	Contains the size of the expanded string buffer.
<b>INIT</b>	N\$ESS number
<b>SIZE</b>	1 byte
<b>ACCESS</b>	\$FETCH dst,ESS,reg ;ESS field to 1-byte dst \$STORE src,ESS,reg ;1-byte src to ESS field \$COMPARE src,ESS,reg ;1-byte src with ESS field
<b>INPUT</b>	CREATE Expanded string buffer size (bytes) ERASE Expanded string buffer size (bytes) OPEN Expanded string buffer size (bytes) PARSE Expanded string buffer size (bytes) RENAME Expanded string buffer size (bytes)

6.5.5 FID Field in NAM Block

<b>USE</b>	Contains the file identifier for the target file.	
<b>INIT</b>	None	
<b>SIZE</b>	3 words	
<b>ACCESS</b>	\$FETCH dst,FID,reg ;FID field to 3-word dst	
<b>INPUT</b>	OPEN	File identifier
<b>OUTPUT</b>	CREATE	File identifier
	ERASE	File identifier
	OPEN	File identifier
	SEARCH	File identifier (only if FB\$FID mask is set)

**CONTROL BLOCK FIELDS  
NAM BLOCK SUMMARY**

**6.5.6 FNB Field in NAM Block**

**USE** Indicates which parts of the merged string were taken from the file string or the default string. (The masks in this section do not include the NB\$WCH mask, which has its own description in the next section.)

**INIT** None

**SIZE** 1 word

**ACCESS** \$TESTBITS mask,FNB,reg ;Test mask bits in FNB field  
\$FETCH dst,FNB,reg ;FNB field to 1-word dst  
\$COMPARE src,FNB,reg ;1-word src with FNB field

**MASKS**

NB\$DEV Device in file string or default string  
NB\$DIR Directory in file string or default string  
NB\$NAM File name in file string or default string  
NB\$NOD Node in file string or default string  
NB\$QUO Quoted string in file string or default string  
NB\$TYP File type in file string or default string  
NB\$VER File version in file string or default string  
NB\$WDI Wildcard directory in file string or default string  
NB\$WNA Wildcard file name in file string or default string  
NB\$WTY Wildcard file type in file string or default string  
NB\$WVE Wildcard file version in file string or default string

**OUTPUT**

CREATE File specification mask  
ERASE File specification mask  
OPEN File specification mask  
PARSE File specification mask  
RENAME File specification mask

6.5.7 FNB Field in NAM Block (NB\$WCH Mask)

<b>USE</b>	Indicates that a valid wildcard context exists. (Masks for the FNB field other than the NB\$WCH mask are described in the previous section.)	
<b>INIT</b>	None	
<b>SIZE</b>	1 word	
<b>ACCESS</b>	\$TESTBITS mask,FNB,reg ;Test mask bits in FNB field \$FETCH dst,FNB,reg ;FNB field to 1-word dst \$COMPARE src,FNB,reg ;1-word src with FNB field	
<b>INPUT</b>	ERASE	Wildcard context established
	OPEN	Wildcard context established
	RENAME	Wildcard context established
	SEARCH	Wildcard context established
<b>OUTPUT</b>	CREATE	Wildcard context established
	OPEN	Wildcard context established
	PARSE	Wildcard context established
	SEARCH	Wildcard context established

**CONTROL BLOCK FIELDS  
NAM BLOCK SUMMARY**

**6.5.8 RSA Field in NAM Block**

<b>USE</b>	Contains the address of the resultant string buffer.
<b>INIT</b>	N\$RSA address
<b>SIZE</b>	1 word
<b>ACCESS</b>	\$FETCH dst,RSA,reg ;RSA field to 1-word dst \$STORE src,RSA,reg ;1-word src to RSA field \$COMPARE src,RSA,reg ;1-word src with RSA field
<b>INPUT</b>	SEARCH Resultant string buffer address

6.5.9 RSL Field in NAM Block

<b>USE</b>	Contains the length of the resultant string.	
<b>INIT</b>	None	
<b>SIZE</b>	1 byte	
<b>ACCESS</b>	\$FETCH dst,RSL,reg	;RSL field to 1-byte dst
	\$COMPARE src,RSL,reg	;1-byte src with RSL field
<b>INPUT</b>	SEARCH	Resultant string length (bytes)
<b>OUTPUT</b>	SEARCH	Resultant string length (bytes)

**CONTROL BLOCK FIELDS  
NAM BLOCK SUMMARY**

**6.5.10 RSS Field in NAM Block**

<b>USE</b>	Contains the size of the resultant string buffer.
<b>INIT</b>	N\$RSS number
<b>SIZE</b>	1 byte
<b>ACCESS</b>	\$FETCH dst,RSS,reg ;RSS field to 1-byte dst \$STORE src,RSS,reg ;1-byte src to RSS field \$COMPARE src,RSS,reg ;1-byte src with RSS field
<b>INPUT</b>	SEARCH Resultant string buffer size (bytes)

6.5.11 WCC Field in NAM Block

<b>USE</b>	Contains wildcard context information.	
<b>INIT</b>	None	
<b>SIZE</b>	1 word	
<b>ACCESS</b>	\$FETCH dst,WCC,reg	;WCC field to 1-word dst
	\$COMPARE src,WCC,reg	;1-word src with WCC field
<b>INPUT</b>	SEARCH	Wildcard context
<b>OUTPUT</b>	PARSE	Wildcard context
	SEARCH	Wildcard context

CONTROL BLOCK FIELDS  
NAM BLOCK SUMMARY

6.5.12 WDI Field in NAM Block

<b>USE</b>	Contains wildcard directory context information.	
<b>INIT</b>	None	
<b>SIZE</b>	1 word	
<b>ACCESS</b>	\$FETCH dst,WDI,reg	;WDI field to 1-word dst
	\$COMPARE src,WDI,reg	;1-word src with WDI field
<b>INPUT</b>	SEARCH	Wildcard directory context
<b>OUTPUT</b>	PARSE	Wildcard directory context
	SEARCH	Wildcard directory context

6.6 PRO BLOCK SUMMARY

This section summarizes the PRO block and its fields. Table 6-6 summarizes the entire block, giving the offset, offset symbol, size, and a brief description for each field; for a field that has mask or code symbols, the table also gives the value, symbol, and a brief description for each mask or code.

Table 6-6: PRO Block Summary

Offset	Offset Symbol	Field Size	Description
000	O\$COD	1 byte	PRO block identifier 000003 XB\$PRO PRO block identifier code
001	O\$BLN	1 byte	PRO block length (bytes) 000012 XB\$PRL PRO block length (bytes)
002	O\$NXT	1 word	Next XAB address
004	O\$PRG	1 word	Programmer or member portion of file owner code
006	O\$PRJ	1 word	Project or group portion of file owner code
010	O\$PRO	1 word	File protection code

**CONTROL BLOCK FIELDS  
PRO BLOCK SUMMARY**

**6.6.1 BLN Field in PRO Block (XB\$PRL Code)**

<b>USE</b>	Contains the length of the PRO block.
<b>INIT</b>	None
<b>SIZE</b>	1 byte
<b>ACCESS</b>	\$FETCH dst,BLN,reg ;BLN field to 1-byte dst \$COMPARE src,BLN,reg ;1-byte src with BLN field

6.6.2 COD Field in PRO Block (XB\$PRO Code)

<b>USE</b>	Contains the identifier for the PRO block.	
<b>INIT</b>	None	
<b>SIZE</b>	1 byte	
<b>ACCESS</b>	\$FETCH dst,COD,reg	;COD field to 1-byte dst
	\$COMPARE src,COD,reg	;1-byte src with COD field

**CONTROL BLOCK FIELDS  
PRO BLOCK SUMMARY**

**6.6.3 NXT Field in PRO Block**

<b>USE</b>	Contains the address of the next XAB (ALL, DAT, KEY, PRO, or SUM block) in a chain of XABs.	
<b>INIT</b>	X\$NXT address	
<b>SIZE</b>	1 word	
<b>ACCESS</b>	\$FETCH dst,NXT,reg	;NXT field to 1-word dst
	\$STORE src,NXT,reg	;1-word src to NXT field
	\$COMPARE src,NXT,reg	;1-word src with NXT field
<b>INPUT</b>	CLOSE	Next XAB address
	CREATE	Next XAB address
	DISPLAY	Next XAB address
	ERASE	Next XAB address
	EXTEND	Next XAB address
	OPEN	Next XAB address
	PARSE	Next XAB address
	RENAME	Next XAB address
	SEARCH	Next XAB address

6.6.4 PRG Field in PRO Block

<b>USE</b>	Contains the member or programmer portion of the file owner code.
<b>INIT</b>	X\$PRG number
<b>SIZE</b>	1 word
<b>ACCESS</b>	\$FETCH dst,PRG,reg ;PRG field to 1-word dst \$STORE src,PRG,reg ;1-word src to PRG field \$COMPARE src,PRG,reg ;1-word src with PRG field
<b>OUTPUT</b>	OPEN Programmer or member portion of file owner code

**CONTROL BLOCK FIELDS  
PRO BLOCK SUMMARY**

**6.6.5 PRJ Field in PRO Block**

<b>USE</b>	Contains the group or project portion of the file owner code.
<b>INIT</b>	X\$PRJ number
<b>SIZE</b>	1 word
<b>ACCESS</b>	\$FETCH dst,PRJ,reg ;PRJ field to 1-word dst \$STORE src,PRJ,reg ;1-word src to PRJ field \$COMPARE src,PRJ,reg ;1-word src with PRJ field
<b>OUTPUT</b>	OPEN Project or group portion of file owner code

6.6.6 PRO Field in PRO Block

<b>USE</b>	Contains the protection code for the file.	
<b>INIT</b>	X\$PRO number	
<b>SIZE</b>	1 word	
<b>ACCESS</b>	\$FETCH dst,PRO,reg	;PRO field to 1-word dst
	\$STORE src,PRO,reg	;1-word src to PRO field
	\$COMPARE src,PRO,reg	;1-word src with PRO field
<b>INPUT</b>	CREATE	File protection code
<b>OUTPUT</b>	OPEN	File protection code

CONTROL BLOCK FIELDS  
RAB SUMMARY

6.7 RAB SUMMARY

This section summarizes the RAB and its fields. Table 6-7 summarizes the entire block, giving the offset, offset symbol, size, and a brief description for each field; for a field that has mask or code symbols, the table also gives the value, symbol, and a brief description for each mask or code.

Table 6-7: RAB Summary

Offset	Offset Symbol	Field Size	Description
000	O\$BID	1 byte	RAB identifier code 000001 RB\$BID RAB identifier
001	O\$BLN	1 byte	RAB length (bytes) 000120 RB\$BLN RAB length (bytes)
002	O\$CTX	1 word	User context
004	O\$ISI	1 word	Internal stream identifier
006	O\$STS	1 word	Completion status code
010	O\$STV	1 word	Completion status value
012	O\$RFA	3 words	Record file address
020	O\$RAC	1 byte	Record access code 000000 RB\$SEQ Sequential access 000001 RB\$KEY Key access 000002 RB\$RFA RFA access
021	O\$KSZ	1 byte	Key size (bytes)
022	O\$ROP	1 word	Record processing option mask 000001 RB\$EOF Position to end-of-file 000002 RB\$MAS Mass insert 000020 RB\$LOA Honor bucket fill numbers 000100 RB\$LOC Locate mode 002000 RB\$KGE Greater-than-or-equal key criterion 004000 RB\$KGT Greater-than key criterion 010000 RB\$FDL Fast deletion 020000 RB\$UIF Update if record exists
024	O\$USZ	1 word	User buffer size (bytes)
026	O\$UBF	1 word	User buffer address
030	O\$RSZ	1 word	Record size (bytes)
032	O\$RBF	1 word	Record buffer address
034	O\$KBF	1 word	Key buffer address
036	O\$KRF	1 byte	Key of reference
037	O\$MBF	1 byte	Multibuffer count
040	O\$MBC	1 byte	Multiblock count
041	O\$RT1A	1 byte	Reserved
042	O\$RHB	1 word	VFC control buffer address
044	O\$FAB	1 word	FAB address
046	O\$BKT	2 words	Virtual block number (VBN) or relative record number (RRN)

6.7.1 BID Field in RAB (RB\$BID Code)

**USE**            Contains the identifier for the RAB.

**INIT**            None

**SIZE**            1 byte

**ACCESS**        \$FETCH dst,BID,reg        ;BID field to 1-byte dst  
                  \$COMPARE src,BID,reg    ;1-byte src with BID field

CONTROL BLOCK FIELDS  
RAB SUMMARY

6.7.2 BKT Field in RAB

USE	Contains a virtual block number or relative record number for a target record.	
INIT	R\$BKT number	
SIZE	2 words	
ACCESS	\$FETCH dst,BKT,reg	;BKT field to 2-word dst
	\$STORE src,BKT,reg	;2-word src to BKT field
	\$FETCH dst,BKTn,reg	;BKT word n to 1-word dst
	\$STORE src,BKTn,reg	;1-word src to BKT word n
	\$COMPARE src,BKTn,reg	;1-word src with BKT word n
INPUT	READ	Virtual block number (VBN)
	WRITE	Virtual block number (VBN)
OUTPUT	FIND	Relative record number (RRN)
	GET	Relative record number (RRN)
	PUT	Relative record number (RRN)

6.7.3 BLN Field in RAB (RB\$BLN Code)

<b>USE</b>	Contains the length of the RAB.
<b>INIT</b>	None
<b>SIZE</b>	1 byte
<b>ACCESS</b>	\$FETCH dst, BLN, reg ;BLN field to 1-byte dst \$COMPARE src, BLN, reg ;1-byte src with BLN field

**CONTROL BLOCK FIELDS**  
**RAB SUMMARY**

**6.7.4 CTX Field in RAB**

**USE**            Contains any information you may want to associate with  
                 the stream at run time.

**INIT**           R\$CTX number

**SIZE**           1 word

**ACCESS**        \$FETCH dst,CTX,reg        ;CTX field to 1-word dst  
                 \$STORE src,CTX,reg       ;1-word src to CTX field  
                 \$COMPARE src,CTX,reg     ;1-word src with CTX field

6.7.5 FAB Field in RAB

<b>USE</b>	Contains the address of the FAB for the target file.
<b>INIT</b>	R\$FAB address
<b>SIZE</b>	1 word
<b>ACCESS</b>	\$FETCH dst,FAB,reg ;FAB field to 1-word dst \$STORE src,FAB,reg ;1-word src to FAB field \$COMPARE src,FAB,reg ;1-word src with FAB field
<b>INPUT</b>	CONNECT FAB address

CONTROL BLOCK FIELDS  
RAB SUMMARY

6.7.6 ISI Field in RAB

USE	Contains the internal stream identifier for the target file.	
INIT	None	
SIZE	1 word	
ACCESS	\$FETCH dst,ISI,reg	;ISI field to 1-word dst
	\$COMPARE src,ISI,reg	;1-word src with ISI field
INPUT	DELETE	Internal stream identifier
	DISCONNECT	Internal stream identifier
	FIND	Internal stream identifier
	FLUSH	Internal stream identifier
	FREE	Internal stream identifier
	GET	Internal stream identifier
	PUT	Internal stream identifier
	READ	Internal stream identifier
	REWIND	Internal stream identifier
	TRUNCATE	Internal stream identifier
	UPDATE	Internal stream identifier
	WRITE	Internal stream identifier
OUTPUT	CONNECT	Internal stream identifier
	DISCONNECT	Internal stream identifier

6.7.7 KBF Field in RAB

<b>USE</b>	Contains the address of the key buffer for the target record.		
<b>INIT</b>	R\$KBF address		
<b>SIZE</b>	1 word		
<b>ACCESS</b>	\$FETCH dst,KBF,reg		;KBF field to 1-word dst
	\$STORE src,KBF,reg		;1-word src to KBF field
	\$COMPARE src,KBF,reg		;1-word src with KBF field
<b>INPUT</b>	FIND	Key buffer	address
	GET	Key buffer	address
	PUT	Key buffer	address

**CONTROL BLOCK FIELDS  
RAB SUMMARY**

**6.7.8 KRF Field in RAB**

**USE**            Contains the index reference number of the index for the operation.

**INIT**           R\$KRF number

**SIZE**           1 byte

**ACCESS**        \$FETCH dst,KRF,reg        ;KRF field to 1-byte dst  
                 \$STORE src,KRF,reg        ;1-byte src to KRF field  
                 \$COMPARE src,KRF,reg       ;1-byte src with KRF field

**INPUT**        CONNECT        Key of reference  
                 FIND            Key of reference  
                 GET             Key of reference  
                 REWIND        Key of reference

6.7.9 K SZ Field in RAB

**USE**            Contains the size of the record key for the operation.

**INIT**           R\$KSZ number

**SIZE**           1 byte

**ACCESS**        \$FETCH dst,KSZ,reg        ;KSZ field to 1-byte dst  
                 \$STORE src,KSZ,reg        ;1-byte src to KSZ field  
                 \$COMPARE src,KSZ,reg       ;1-byte src with KSZ field

**INPUT**        FIND            Key size (bytes)  
                 GET             Key size (bytes)  
                 PUT             Key size (bytes)

CONTROL BLOCK FIELDS  
RAB SUMMARY

6.7.10 MBC Field in RAB

USE	Contains the multiblock count for the stream.
INIT	R\$MBC number
SIZE	1 byte
ACCESS	\$FETCH dst,MBC,reg ;MBC field to 1-byte dst \$STORE src,MBC,reg ;1-byte src to MBC field \$COMPARE src,MBC,reg ;1-byte src with MBC field
INPUT	CONNECT Multiblock count

6.7.11 MBF Field in RAB

**USE**            Contains the multibuffer count for the stream.

**INIT**           R\$MBF number

**SIZE**           1 byte

**ACCESS**        \$FETCH dst,MBF,reg        ;MBF field to 1-byte dst  
                 \$STORE src,MBF,reg        ;1-byte src to MBF field  
                 \$COMPARE src,MBF,reg       ;1-byte src with MBF field

**INPUT**         CONNECT        Multibuffer count

**CONTROL BLOCK FIELDS**  
**RAB SUMMARY**

**6.7.12 RAC Field in RAB**

**USE**            Contains the access mode code for the operation.

**INIT**           R\$RAC code

**SIZE**           1 byte

**ACCESS**        \$FETCH dst,RAC,reg        ;RAC field to 1-byte dst  
                 \$STORE src,RAC,reg        ;1-byte src to RAC field  
                 \$COMPARE src,RAC,reg     ;1-byte src with RAC field

**CODES**        RB\$KEY    Key access  
                 RB\$RFA    RFA access  
                 RB\$SEQ    Sequential access

**INPUT**        FIND            Record access code  
                 GET            Record access code  
                 PUT            Record access code

6.7.13 RBF Field in RAB

<b>USE</b>	Contains the address of the record buffer for the operation.	
<b>INIT</b>	R\$RBF address	
<b>SIZE</b>	1 word	
<b>ACCESS</b>	\$FETCH dst,RBF,reg	;RBF field to 1-word dst
	\$STORE src,RBF,reg	;1-word src to RBF field
	\$COMPARE src,RBF,reg	;1-word src with RBF field
<b>INPUT</b>	PUT	Record buffer address
	UPDATE	Record buffer address
	WRITE	Record buffer address
<b>OUTPUT</b>	CONNECT	Record buffer address
	GET	Record buffer address
	PUT	Record buffer address
	READ	Record buffer address

**CONTROL BLOCK FIELDS  
RAB SUMMARY**

**6.7.14 RFA Field in RAB**

<b>USE</b>	Contains the record file address for the target record.	
<b>INIT</b>	None	
<b>SIZE</b>	3 words	
<b>ACCESS</b>	\$FETCH dst,RFA,reg ;RFA field to 3-word dst	
<b>INPUT</b>	FIND	Record file address
	GET	Record file address
<b>OUTPUT</b>	CONNECT	End-of-file address
	FIND	Record file address
	GET	Record file address
	PUT	Record file address
	READ	Virtual block number (2 words)
	WRITE	Virtual block number (2 words)

6.7.15 RHB Field in RAB

**USE**            Contains the address of the VFC fixed control area buffer  
                  for the target record.

**INIT**            R\$RHB address

**SIZE**            1 word

**ACCESS**        \$FETCH dst,RHB,reg        ;RHB field to 1-word dst  
                  \$STORE src,RHB,reg        ;1-word src to RHB field  
                  \$COMPARE src,RHB,reg        ;1-word src with RHB field

**INPUT**        GET            VFC control buffer address  
                  PUT            VFC control buffer address  
                  UPDATE        VFC control buffer address

**CONTROL BLOCK FIELDS**  
**RAB SUMMARY**

**6.7.16 ROP Field in RAB (RB\$EOF Mask)**

**USE**            Requests initial stream context at end-of-file.

**INIT**           R\$ROP mask

**SIZE**           1 word

**ACCESS**        \$SET mask,ROP,reg        ;Mask bits on in ROP field  
                 \$OFF mask,ROP,reg        ;Mask bits off in ROP field  
                 \$TESTBITS mask,ROP,reg ;Test mask bits in ROP field  
                 \$FETCH dst,ROP,reg       ;ROP field to 1-word dst  
                 \$STORE src,ROP,reg       ;1-word src to ROP field  
                 \$COMPARE src,ROP,reg     ;1-word src with ROP field

**INPUT**         CONNECT        Position to end-of-file

6.7.17 ROP Field in RAB (RB\$FDL Mask)

USE Requests fast deletion.

INIT R\$ROP mask

SIZE 1 word

ACCESS \$SET mask,ROP,reg ;Mask bits on in ROP field  
\$OFF mask,ROP,reg ;Mask bits off in ROP field

                 GET                User buffer size (bytes)  
                 PUT                User buffer size (bytes)  
                 READ               User buffer size (bytes)

6.8 SUM BLOCK SUMMARY

This section summarizes the SUM block and its fields. Table 6-8 summarizes the entire block, giving the offset, offset symbol, size, and a brief description for each field; for a field that has mask or code symbols, the table also gives the value, symbol, and a brief description for each mask or code.

Table 6-8: SUM Block Summary

Offset	Offset Symbol	Field Size	Description
000	O\$COD	1 byte	SUM block identifier 000005 XB\$SUM SUM block identifier code
001	O\$BLN	1 byte	SUM block length (bytes) 000012 XB\$SML SUM block length (bytes)
002	O\$NXT	1 word	Next XAB address
004	O\$NOK	1 byte	Number of indexes
005	O\$NOA	1 byte	Number of areas
006	O\$NOR	1 byte	Reserved
007		1 byte	Reserved
010	O\$PVN	1 word	Prologue version number

**CONTROL BLOCK FIELDS**  
**SUM BLOCK SUMMARY**

**6.8.1 BLN Field in SUM Block (XB\$SML Code)**

<b>USE</b>	Contains the length of the SUM block.
<b>INIT</b>	None
<b>SIZE</b>	1 byte
<b>ACCESS</b>	\$FETCH dst,BLN,reg ;BLN field to 1-byte dst \$COMPARE src,BLN,reg ;1-byte src with BLN field

6.8.2 COD Field in SUM Block (XB\$SUM Code)

<b>USE</b>	Contains the identifier for the SUM block.
<b>INIT</b>	None
<b>SIZE</b>	1 byte
<b>ACCESS</b>	\$FETCH dst,COD,reg ;COD field to 1-byte dst \$COMPARE src,COD,reg ;1-byte src with COD field

**CONTROL BLOCK FIELDS**  
**SUM BLOCK SUMMARY**

**6.8.3 NOA Field in SUM Block**

<b>USE</b>	Contains the number of areas in the file.	
<b>INIT</b>	None	
<b>SIZE</b>	1 byte	
<b>ACCESS</b>	\$FETCH dst,NOA,reg	;NOA field to 1-byte dst
	\$COMPARE src,NOA,reg	;1-byte src with NOA field
<b>OUTPUT</b>	DISPLAY	Number of areas
	OPEN	Number of areas

6.8.4 NOK Field in SUM Block

<b>USE</b>	Contains the number of indexes in the file.
<b>INIT</b>	None
<b>SIZE</b>	1 byte
<b>ACCESS</b>	\$FETCH dst,NOK,reg ;NOK field to 1-byte dst \$COMPARE src,NOK,reg ;1-byte src with NOK field
<b>OUTPUT</b>	DISPLAY Number of indexes OPEN Number of indexes

CONTROL BLOCK FIELDS  
SUM BLOCK SUMMARY

6.8.5 NXT Field in SUM Block

<b>USE</b>	Contains the address of the next XAB (ALL, DAT, KEY, PRO, or SUM block) in a chain of XABs.	
<b>INIT</b>	X\$NXT address	
<b>SIZE</b>	1 word	
<b>ACCESS</b>	\$FETCH dst,NXT,reg	;NXT field to 1-word dst
	\$STORE src,NXT,reg	;1-word src to NXT field
	\$COMPARE src,NXT,reg	;1-word src with NXT field
<b>INPUT</b>	CLOSE	Next XAB address
	CREATE	Next XAB address
	DISPLAY	Next XAB address
	ERASE	Next XAB address
	EXTEND	Next XAB address
	OPEN	Next XAB address
	PARSE	Next XAB address
	RENAME	Next XAB address
	SEARCH	Next XAB address

6.8.6 PVN Field in SUM Block

<b>USE</b>	Contains the prologue version number for the file.
<b>INIT</b>	None
<b>SIZE</b>	1 word
<b>ACCESS</b>	\$FETCH dst,PVN,reg ;PVN field to 1-word dst \$COMPARE src,PVN,reg ;1-word src with PVN field
<b>OUTPUT</b>	DISPLAY Prologue version number OPEN Prologue version number

**CHAPTER 7**  
**EXAMPLE PROGRAMS**

This chapter contains example programs; the titles of the programs are:

- PARSE - \$PARSE TEST
- SEARCH - \$SEARCH TEST
- ERASE - \$ERASE TEST
- RENAME - \$RENAME TEST
- GSA - CORE SPACE ALLOCATOR

Sections 7.1 through 7.4 contain these programs and give instructions for building and running them.

NOTE

References to [ppn] in the command lines in the following sections indicate that you should include your default PPN.

Each program requires the GSA routine (Section 7.5) for allocating dynamic memory:

```
RUN $MAC.TSK
MAC> SY:GSA=LB:RSMAC/ML,SY:[ppn]GSA
MAC> ^Z
```

## EXAMPLE PROGRAMS

### 7.1 PARSE - \$PARSE TEST

The following shows how to build the PARSE program (Example 7-1) and shows a brief sample run of the program.

```
RUN $MAC.TSK
MAC>SY:PARSE=LB:RSMAC/ML,SY:[ppn]PARSE
MAC>^Z
RUN $TKB.TSK
TKB>SY:PARSE=SY:PARSE,SY:GSA
TKB>LB:SYSLIB/LB:INIDM:EXTSK
TKB>LB:RMSLIB/LB
TKB>//
RUN PARSE
Enter the default name string: DM0:
Enter the primary name string: .LOG
$PARSE expanded string is DM0:[1,51].LOG
      File name bits (FNB) are 004302
      (DEV, TYP, DIR)
Enter the default name string: ^Z
```

## Example 7-1: PARSE - \$PARSE Test

## EXAMPLE PROGRAMS

### 7.5 GSA -- CORE SPACE ALLOCATOR

#### Example 7-5: GSA - Core Space Allocator

```
.Title  GSA - Core space allocator
.Ident  /V02.00/

.Enabl  LC

;
; Copyright (C) 1982,   Digital Equipment Corporation
;                               Maynard, Massachusetts 01754
;
; **-GSA - Dynamic memory allocation for RMS-11 pool
;
;
; Called by RMS-11 to manage pool space.
; In the event of pool exhaustion, the task
; image will be extended to obtain more space.
;
; May be called by user written code providing
; the interface standard is adhered to.
;
; Interface:
;   Request space:
;     R0 ->  RMS/user Pool list head (maintained by RL/CQB)
;     R1 :=  Amount of space requested (bytes)
;     R2 :=  0 (differentiates between request and release)
;
;   Release space:
;     R0 ->  RMS Pool list head (maintained by RL/CQB)
;     R1 :=  Amount of space to be released (bytes)
;     R2 ->  Base address (for release)
;
;
; Returns:
;   C-Bit "set"   if an error has occurred (failure)
;   C-Bit "clear" if no error has occurred (success)
;

.Mcall  Extk$$

;
; GSA internal data:
;
;   GSABAS - Base address for the next memory allocation.
;           Initially set to zero, it will be assigned
;           the first address outside of the task's
;           current address limits.
;   GSAMIN - Decimal value reflecting the minimum size
;           (in bytes) to extend the task in order to
;           provide space to the pool.
;   GSAREQ - Requested pool block number.  If a request
;           for the 'GSAMIN' fails, then the original
;           allocation size will be attempted.  If that
;           fails, then there is no more memory left.
```

```

; GSA Initialization
;
; This code is entered when GSA is entered with GSABAS
; set to zero. In order to be able to build valid pool
; header tables, GSABAS must be properly initialized and
; maintained.
;
; Initialization consists of finding the size of the task
; in 32-word units, and converting that value to a usable
; 16-bit address (which corresponds to the address of the
; next task extension (Extk$$) call. Once GSABAS has been
; initialized, GSAINI will not be reused.
;
GSAINI:
    Mov      R0,-(SP)      ; R0-2 will be used to
    Mov      R1,-(SP)      ; communicate with $INIDM
    Mov      R2,-(SP)      ; NOTE: $INIDM uses EXTSK.

;
; The following code will use $INIDM to initialize the
; dynamic memory. As documented, R1 will return
; the first address following the task image, and R2 will
; return the size of the "free" memory from that address.
;
; NOTE: $INIDM and EXTSK reside in LB:[1,1]VMLIB for RSX
;       systems, and in LB:SYSLIB for RSTS/E systems.
;
; $INIDM interface:
;   Calls:
;     R0 -> Pool list head
;
;   Returns:
;     R0 -> First address in task
;     R1 -> First address AFTER task
;     R2 := Size of free core after task (based at R1)
;
    Call     $INIDM        ; Initialize dynamic memory
    Mov      R1,GSABAS     ; Setup the "free" address
    Mov      (SP)+,R2      ; Restore the registers
    Mov      (SP)+,R1      ;
    Mov      (SP)+,R0      ;
    Return                    ; And return to GSA

    .Page

```

EXAMPLE PROGRAMS

```

;
; GSA Mainline
;
;   Entry point is "GSA", with registers 0-2 loaded as
;   described above.
;
GSA::

;
; First, determine if dynamic memory has been initialized.
; GSABAS (initially set to zero) will be non-zero if $INIDM
; has been called and the memory list initialized. On RSX
; based systems it is possible to install tasks with an
; extension (/INCREMENT). $INIDM will detect this and setup
; the first memory entry in the pool list.
;
; A point to note: If the RSX task has been installed with
; the non-checkpointable (/CP) flag, then EXTKs will not
; return success. If it is necessary to install the task
; non-checkpointable, then the task should be installed with
; an increment value.
;

      Tst      GSABAS          ; Dynamic memory initialized?
      Bne     10$             ; Yes if NE, proceed
      Call    GSAINI         ; Otherwise, initialize pool

10$:

;
; Determine if this call involves real memory.
; R1 should contain the size (in bytes) of the core
; block requested or to be released. If zero then
; return to the caller without an error (TST leaves CC).
;

      Tst     R1              ; Real memory?
      Bne    20$             ; Yes if NE, then process it
      Return                               ; Otherwise return with success

20$:

;
; If this call is a request for space, pass control
; to the allocation routines. Otherwise, pass control
; to the system deallocation module $RLCB. There is
; no need to return, so control is passed via JMP.
; Note that module RQLCB resides in LB:[1,1]SYSLIB
; for RSX11M/M-PLUS and LB:SYSLIB for RSTS/E.

      Tst     R2              ; Address specified? (release)
      Beq    30$             ; No if EQ, then it's a request
      Jmp    $RLCB          ; Otherwise it's a release; do it

30$:

;
; Save our current context:
; R0 = Pool list head
; R1 = Size of memory required
; R2 = 0 (signifies request)
;

      Mov     R0,-(SP)
      Mov     R1,-(SP)
      Mov     R2,-(SP)

```

```

;
; Attempt an allocation from the current pool
; If this is successful, pass control to the
; common exit.
;

        Call    $RQCB          ; Try the allocation
        Bcc     70$            ; CC signifies success

;
; Now that the initial allocation failed, we must extend
; the task and give the new area (extended into) to the
; caller. To do this, the following procedure is used:
;
;     1. The task is extended
;     2. The area extended is returned to the
;        pool specified as if a release was attempted
;     3. We retry the allocation operation, but
;        this time it should succeed, since we have
;        increased the size of the pool area
;
; NOTE: $RQCB has a bad habit of nuking registers, so it
; becomes necessary to save and restore them around
; unsuccessful calls.
;

        Mov     2(SP),R1       ; Obtain the request size

;
; Determine what the requirement is in 32-word blocks.
; Retain this value to allow GSA to decide whether
; to issue further task extension directives in
; order to satisfy the requirements.
;

        Add     #63.,R1        ; Round the request
        Asr     R1              ; to a 32-word boundary
        Asr     R1              ; Then convert the value
        Asr     R1              ; to the number of
        Asr     R1              ; 32-word blocks.
        Asr     R1
        Asr     R1
        Mov     R1,GSAREQ      ; Save the real size

;
; We will allocate core to the pool in "reasonable"
; increments to cut down on system overhead, and pool
; fragmentation. This is accomplished by using either
; the requested size, or "GSAMIN", whichever is LARGER.
; If the request is unsuccessful, and the amount is
; smaller than GSAMIN, then request that particular size.
;

        Cmp     R1,GSAMIN      ; Smaller than minimum?
        Bhi     40$            ; No if HI, use it as is
        Mov     GSAMIN,R1      ; Otherwise use GSAMIN
40$:

;
; Now we attempt to extend the task by that size.
; If the request fails, then use the size of the
; original request. If that also fails, then we
; simply ran out of memory.
;

        Extk$$ R1              ; Extend the task

```

EXAMPLE PROGRAMS

```

        Bcc      60$           ; CC if successful
        Cmp      R1,GSAREQ    ; Is this request?
        Blos     50$           ; Yes if LOS, the end
        Mov      GSAREQ,R1    ; Otherwise try to use
        Br       40$           ; the actual request
50$:
        Sec
        Br       70$           ; Mark failure
                                   ; And exit

;
; The task has been extended, now this memory must be
; released to the pool for future allocation.
; To do this, we setup the registers as if RMS were
; going to release the core, and call ourself to do
; the work. When the area has been released to the
; pool, we will return inline and proceed to reenter
; our code again from start to reattempt the allocation.
;

60$:
        Mov      4(SP),R0     ; Setup the PLH
        Asl      R1           ; Convert the real
        Asl      R1           ; size to the actual
        Asl      R1           ; 16-bit size that
        Asl      R1           ; was allocated.
        Asl      R1           ; The virtual address
        Asl      R1           ; should be after the
        Mov      GSABAS,R2    ; task (which is now
        Add      R1,GSABAS    ; part of the task)
        Call     GSA          ; Call ourself to release

;
; At this point, the new memory has been added to the
; pool, and is available for use. We now reattempt
; to allocate the memory required.
;

        Mov      (SP)+,R2     ; Restore our registers
        Mov      (SP)+,R1     ; to the initial state
        Mov      (SP)+,R0     ; upon entry, and reenter
        Br       GSA          ; as if it's a new request

;
; Common exit. Leave the registers in their current state,
; and return control to the caller.
;

70$:
        Inc      (SP)+        ; These won't alter the
        Bit      (SP)+,(SP)+ ; C-bit, so status remains
        Return
                                   ; unchanged upon return

        .End

```

# COMPLETION CODES AND FATAL ERROR CODES

- ER\$ACT Activity precludes operation** Octal: 177720  
Decimal: -48
- RMS-11 could not perform the requested operation because of an activity in progress (for example, RMS-11 cannot perform the CLOSE operation for a file that has an outstanding asynchronous operation).
- ER\$AID Bad value in AID field** Octal: 177700  
Decimal: -64
- The file contains no area with the area number given in the AID field of an ALL block.
- ER\$ALN Bad mask in ALN field** Octal: 177660  
Decimal: -80
- The ALN field of an ALL block contains an invalid value.
- ER\$ALQ Bad value in ALQ field** Octal: 177640  
Decimal: -96
- The ALQ field of a FAB or an ALL block contains an invalid value; the value in the ALQ field is either too large, or is 0 for an EXTEND operation.
- ER\$ANI Bad ANSI-format magtape file** Octal: 177620  
Decimal: -112
- The records in an ANSI-format magtape file are variable-length, but are not in the proper ANSI-D format.
- ER\$AOP Bad mask in AOP field** Octal: 177600  
Decimal: -128
- The AOP field of an ALL block contains an invalid mask value.
- ER\$ATR Error reading attributes** Octal: 177540  
Decimal: -160
- The file processor could not read the attributes for the file. The STV field of the FAB or RAB contains the file processor error code; see your operating system documentation for the meaning of the code.
- ER\$ATW Error writing attributes** Octal: 177520  
Decimal: -176
- The file processor could not write the attributes for the file. The STV field of the FAB or RAB contains the file processor error code; see your operating system documentation for the meaning of the code.
- ER\$BKS Bad value in BKS field** Octal: 177500  
Decimal: -192
- The value in the BKS field of the FAB is too large.
- ER\$BKZ Bad value in BKZ field** Octal: 177460  
Decimal: -208
- The value in the BKZ field of an ALL block is too large; or the bucket sizes of the lowest (LAN) and upper (IAN) areas of an index are not equal.

COMPLETION CODES AND FATAL ERROR CODES

**ER\$BOF** Beginning-of-file found Octal: 177430  
 Decimal: -232

The SPACE operation backspaced to the beginning-of-file.

**ER\$BPA** Bad address in BPA field Octal: 177420  
 Decimal: -240

The value in the BPA field of the FAB is odd, and the BPS field contains a nonzero value.

**ER\$BPS** Bad value in BPS field Octal: 177400  
 Decimal: -256

The value in the BPS field of the FAB is nonzero and not a multiple of 4, and the BPA field is nonzero.

**ER\$CCR** RAB already in use Octal: 177340  
 Decimal: -288

The CONNECT operation could not connect a stream using the specified RAB because the file is sequential and does not allow multiple connected streams.

**ER\$CHG** Illegal record key change Octal: 177320  
 Decimal: -304

The UPDATE operation did not allow a changed record key because the index does not allow key changes or does not allow duplicate key values.

**ER\$CHK** Bad bucket header Octal: 177300  
 Decimal: -320

The bucket header data for an indexed file is corrupted.

Notify your system manager, who should follow this procedure to recover from the error:

1. Move the disk to a different drive and try the process again. If the process succeeds, the error was a hardware error; report the faulty hardware and continue processing. If the process fails again, proceed to the next step.
2. Recreate the file using an RMS-11 utility (RMSIFL or RMSCNV). If this succeeds, the primary index and data records were free of errors and the new file is valid; continue processing. If this fails, proceed to the next step.
3. Restore the file from a backup copy.

**ER\$CLS** File processor error Octal: 177260  
 Decimal: -336

The file processor returned an error condition to the CLOSE operation. The STV field of the FAB contains the file processor error code; see your operating system documentation for the meaning of the code.

**ER\$COD** Bad code in COD field Octal: 177240  
 Decimal: -352

The value in the COD field of an XAB is not valid.

# COMPLETION CODES AND FATAL ERROR CODES

- ER\$CRE** File processor error Octal: 177220  
Decimal: -368
- The file processor returned an error condition to the CREATE operation. The STV field of the FAB contains the file processor error code; see your operating system documentation for the meaning of the code.
- ER\$CUR** Undefined current-record context Octal: 177200  
Decimal: -384
- A DELETE, TRUNCATE, or UPDATE operation required a defined current-record context, but it was undefined.
- ER\$DAN** Bad value in DAN field Octal: 177140  
Decimal: -416
- The value in the DAN field of a KEY block specifies a nonexistent area.
- ER\$DEL** Record having RFA deleted Octal: 177120  
Decimal: -432
- The record specified by RFA has been deleted.
- ER\$DEV** Bad device specification Octal: 177100  
Decimal: -448
- The device specification given contains a syntax error, there is no such device, the device is inappropriate for the operation, or two different devices have been specified for a RENAME operation.
- ER\$DFW** File processor error Octal: 177070  
Decimal: -456
- The file processor returned an error while writing deferred-write data. The STV field of the FAB or RAB contains the file processor error code; see your operating system documentation for the meaning of the code.
- ER\$DIR** Bad directory specification Octal: 177060  
Decimal: -464
- The directory specification contains a syntax error.
- ER\$DME** Pool exhausted Octal: 177040  
Decimal: -480
- One of the five pools that RMS-11 uses cannot provide needed space for the operation.
- ER\$DNA** Bad address in DNA field Octal: 177030  
Decimal: -488
- The DNA field of the FAB contains 0, but the DNS field is nonzero.
- ER\$DNF** No such directory Octal: 177020  
Decimal: -496
- The directory specification given specifies a nonexistent directory.

COMPLETION CODES AND FATAL ERROR CODES

**ER\$DNR Device not ready** Octal: 177000  
 Decimal: -512

The device specified is not on line.

**ER\$DPE Device positioning error** Octal: 176770  
 Decimal: -520

The file processor could not position the magtape device as specified. The STV field of the FAB or RAB contains the file processor error code; see your operating system documentation for the meaning of the code.

**ER\$DTP Bad code in DTP field** Octal: 176760  
 Decimal: -528

The value in the DTP field of a KEY block does not specify a valid key data type.

**ER\$DUP Duplicate key not allowed** Octal: 176740  
 Decimal: -544

The record offered for insertion had a record key that would duplicate a record already in the index, but the index does not allow duplicate keys.

**ER\$ENV Feature not in selected RMS-11 environment** Octal: 176700  
 Decimal: -576

The RMS-11 environment (selected with the ORG\$ macro or by the compiler or by the manner in which RMS-11 code is linked with your program) does not include the attempted operation for the specified file organization.

**ER\$EOF End-of-file reached** Octal: 176660  
 Decimal: -592

The operation specified a record or block that is past the last record or block.

**ER\$ESA Bad address in ESA field** Octal: 176650  
 Decimal: -600

The ESA field of the NAM block contains 0.

**ER\$ESL Bad value in ESL field** Octal: 176644  
 Decimal: -604

The ESL field of the NAM block contains 0.

**ER\$ESS ESS field value too small** Octal: 176640  
 Decimal: -608

The value in the ESS field of the NAM block specifies an expanded string buffer that is too small to contain the expanded string.

**ER\$EXP File expiration date not yet reached** Octal: 176630  
 Decimal: -616

**ER\$EXT File processor error** Octal: 176620  
 Decimal: -624

The file processor could not make the requested extension to the file. The STV field of the FAB or RAB contains the file

COMPLETION CODES AND FATAL ERROR CODES

**ER\$FNA** Bad address in FNA field Octal: 176470  
 Decimal: -712

The FNA field of the FAB contains 0, but the FNS field is nonzero.

**ER\$FNF** File not found Octal: 176440  
 Decimal: -736

The file specified for a directory or file operation does not exist.

**ER\$FNM** Bad file name Octal: 176420  
 Decimal: -752

The file name portion of a file specification string has a syntax error.

**ER\$FOP** Bad mask in FOP field Octal: 176400  
 Decimal: -768

The FOP field of the FAB contains one or more illegal masks.

**ER\$FSS** Bad merged string Octal: 176370  
 Decimal: -776

The file processor found syntax errors in the merged string. The STV field of the FAB contains the file processor error code; see your operating system documentation for the meaning of the code.

**ER\$FUL** Device or file full Octal: 176360  
 Decimal: -784

The specified device or file has no room to allow file creation or extension.

**ER\$IAN** Bad value in IAN field Octal: 176340  
 Decimal: -800

The value in the IAN field of a KEY block specifies a nonexistent file area.

**ER\$IDX** Index not initialized Octal: 176320  
 Decimal: -816

This code is only returned in the STV field of the RAB in conjunction with the code ER\$RNF in the STS field. It indicates that no entries have been made in the index specified for the GET or FIND operation.

**ER\$IFI** Bad value in IFI field Octal: 176300  
 Decimal: -832

The value in the IFI field of the FAB is not the internal file identifier for a file.

**ER\$IMX** Too many XABs of same type Octal: 176260  
 Decimal: -848

The number of XABs of the same type in the chain of XABs is too large (more than 254 ALL blocks or KEY blocks, more than 1 DAT block, PRO block, or SUM block).

# COMPLETION CODES AND FATAL ERROR CODES

- ER\$IOP** Illegal operation for file Octal: 176220  
Decimal: -880
- The requested operation is illegal for the file organization or for the allowed access.
- ER\$IIRC** Illegal record found in sequential file Octal: 176200  
Decimal: -896
- The record length field of a record in a sequential file is invalid.
- ER\$ISI** Bad value in ISI field Octal: 176160  
Decimal: -912
- The ISI field of the RAB contains a value that is not an internal stream identifier.
- ER\$KBF** Bad address in KBF field Octal: 176140  
Decimal: -928
- The KBF field of the RAB contains 0.
- ER\$KEY** Bad key Octal: 176120  
Decimal: -944
- The key specified for a key access operation is invalid (either a negative RRN or an erroneous packed-decimal key).
- ER\$KRF** Bad value in KRF field Octal: 176100  
Decimal: -960
- The KRF field of the RAB contains (or contained) a value that does not specify a file index. For a key access FIND or GET operation, the RAB contains the invalid value in its KRF field; for a sequential access FIND or GET operation, the RAB contained the invalid value in its KRF field during an earlier CONNECT or REWIND operation.
- ER\$KSZ** Bad value in KSZ field Octal: 176060  
Decimal: -976
- The KSZ field of the RAB contains an invalid value.
- ER\$LAN** Bad value in LAN field Octal: 176040  
Decimal: -992
- The value in the LAN field of a KEY block specifies a nonexistent file area.
- ER\$LBL** Bad magtape label Octal: 176020  
Decimal: -1008
- The magtape does not have a valid ANSI label.
- ER\$LBY** Logical channel busy Octal: 176000  
Decimal: -1024
- The LCH field of the FAB contains the number of a logical channel that is already in use by the task.
- ER\$LCH** Bad value in LCH field Octal: 175760  
Decimal: -1040
- The LCH field of the FAB contains a value that is too large to be a logical channel number.

COMPLETION CODES AND FATAL ERROR CODES

**ER\$LEX** Extension not needed Octal: 175750  
 Decimal: -1048

The requested extension was not needed because the file area still contains an unused extent.

**ER\$LOC** Bad value in LOC field Octal: 175740  
 Decimal: -1056

The LOC field of an ALL block contains a value that does not specify a valid location.

**ER\$MEM** Memory address rollover Octal: 175710  
 Decimal: -1080

The area specified for the file string, default string, expanded string, or resultant string extends beyond the end of addressable memory.

**ER\$MKD** File processor error Octal: 175700  
 Decimal: -1088

The file processor could not mark the specified file for deletion. The STV field of the FAB contains the file processor error code; see your operating system documentation for the meaning of the code.

**ER\$MRN** Bad value in MRN field or bad record number Octal: 175660  
 Decimal: -1104

The MRN field of the FAB contains a negative number (CREATE operation), or the record number specified for a key access record operation is larger than the file maximum record number (specified in the MRN field at file creation).

**ER\$MRS** Bad value in MRS field Octal: 175640  
 Decimal: -1120

The MRS field of the FAB contains 0 even though the file to be created is requested either to be a relative file or to have fixed-length records.

**ER\$NAE** Unmappable network access error Octal: 175630  
 Decimal: -1128

If this error occurs, please submit a Software Performance Report to DIGITAL, including the following information:

- Contents of general registers and stack
- Operation and file organization for which the error occurred
- Task builder map of the task

**ER\$NAM** Bad address in NAM field Octal: 175620  
 Decimal: -1136

The NAM field of the FAB contains 0 or an odd address.

**ER\$NEF** Context not end-of-file Octal: 175600  
 Decimal: -1152

The PUT operation could not insert a record into a sequential file because the next-record context was not the end-of-file.

## COMPLETION CODES AND FATAL ERROR CODES

- ER\$NET Network link lost** Octal: 175570  
Decimal: -1160
- The STV field of the FAB or RAB contains the network error code.
- ER\$NMF No more matching files** Octal: 175554  
Decimal: -1172
- The SEARCH operation ended the wildcard SEARCH series because there are no more files matching the wildcard file specification.
- ER\$NPK No primary key for indexed file** Octal: 175540  
Decimal: -1184
- The CREATE operation did not create the specified file because no primary index was specified even though the request specified indexed file organization.
- ER\$OPN File processor error** Octal: 175520  
Decimal: -1200
- The file processor could not open the specified file. The STV field of the FAB contains the file processor error code; see your operating system documentation for the meaning of the code.
- ER\$ORD Ordering of XABs illegal** Octal: 175500  
Decimal: -1216
- The chain of XABs for a directory or file operation is improperly ordered.
- ER\$ORG Bad mask in ORG field** Octal: 175460  
Decimal: -1232
- The ORG field of the FAB contains an invalid file organization code; the file was not created.
- ER\$PLG Error reading file prologue** Octal: 175440  
Decimal: -1248
- The data read from the file prologue is incorrect.
- Notify your system manager, who should follow this procedure to recover from the error:
1. Move the disk to a different drive and try the process again. If the process succeeds, the error was a hardware error; report the faulty hardware and continue processing. If the process fails again, proceed to the next step.
  2. Recreate the file using an RMS-11 utility (RMSIFL or RMSCNV). If this succeeds, the primary index and data records were free of errors and the new file is valid; continue processing. If this fails, proceed to the next step.
  3. Restore the file from a backup copy.

COMPLETION CODES AND FATAL ERROR CODES

**ER\$RLK Record locked** Octal: 175140  
 Decimal: -1440

The bucket containing the specified record is locked by another task or by another stream in your task.

**ER\$RNF No such record** Octal: 175100  
 Decimal: -1472

The record specified for key access does not exist.

**ER\$RNL Record not locked** Octal: 175060  
 Decimal: -1488

The FREE operation found that no record was locked for the stream.

**ER\$ROP Bad mask in ROP field** Octal: 175040  
 Decimal: -1504

The ROP field of the RAB contained illegal set bits.

**ER\$RPL File processor error** Octal: 175020  
 Decimal: -1520

The data read from the file prologue is incorrect.

Notify your system manager, who should follow this procedure to recover from the error:

1. Move the disk to a different drive and try the process again. If the process succeeds, the error was a hardware error; report the faulty hardware and continue processing. If the process fails again, proceed to the next step.
2. Recreate the file using an RMS-11 utility (RMSIFL or RMSCNV). If this succeeds, the primary index and data records were free of errors and the new file is valid; continue processing. If this fails, proceed to the next step.
3. Restore the file from a backup copy.

**ER\$RRV Bad internal pointer** Octal: 175000  
 Decimal: -1536

An internal pointer in the file is invalid. Reload the file, with RMSCNV or RMSIFL, using its primary index.

**ER\$RSL Bad value in RSL field** Octal: 174754  
 Decimal: -1556

The RSL field of the NAM block contains 0.

**ER\$RSS Bad value in RSS field** Octal: 174750  
 Decimal: -1560

The RSS field of the NAM block contains 0.

**ER\$RST Bad address in RSA field** Octal: 174744  
 Decimal: -1564

The RSA field of the NAM block contains 0.

COMPLETION CODES AND FATAL ERROR CODES

**ER\$RSZ** Bad value in RSZ field Octal: 174740  
Decimal: -1568

The RSZ field of the RAB contains a value that is larger than the maximum allowed record size, or (for fixed-length records) is not equal to the maximum record size, or (for an UPDATE operation to a sequential file) is not equal to the length of the record to be updated.

**ER\$RTB** Record too big for user buffer Octal: 174720  
Decimal: -1584

The record read cannot fit into the user buffer; the STV field of the RAB contains the size of the record, and the portion that will fit is moved to the user buffer as for a successful GET.

**ER\$RVU** Internal pointer corrupted Octal: 174710  
Decimal: -1592

The record insertion succeeded and the primary index was updated successfully; however, RMS-11 could not update internal pointers.

To recover from the error, follow this procedure:

1. Recreate the file using an RMS-11 utility (RMSIFL or RMSCNV). If this succeeds, the primary index and data records were free of errors and the new file is valid; continue processing. If this fails, proceed to the next step.
2. Restore the file from a backup copy.

**ER\$SEQ** Sequential insertion records not in order Octal: 174700  
Decimal: -1600

The sequential access PUT operation found records whose primary keys were not in ascending order.

**ER\$SHR** Bad mask in SHR field Octal: 174660  
Decimal: -1616

The SHR field of the FAB contains an illegal mask.

**ER\$SIZ** Bad value in SIZ field Octal: 174640  
Decimal: -1632

The SIZ field of a KEY block contains an illegal value.

**ER\$SUP** Operation not supported over network Octal: 174610  
Decimal: -1656

The requested operation is not supported over the network.

**ER\$SYS** System error Octal: 174600  
Decimal: -1664

The interface between RMS-11 and the system is in error; the STV field of the FAB or RAB contains the status code for a system directive. Please submit a Software Performance Report.

# COMPLETION CODES AND FATAL ERROR CODES

- ER\$TRE** Index error Octal: 174560  
Decimal: -1680
- The index contains invalid data. Build a new file using either an RMS-11 utility (RMSIFL or RMSCNV) or using sequential access and the primary index to fetch the old records.
- ER\$TYP** Bad file type Octal: 174540  
Decimal: -1696
- The file type in a file specification contains invalid syntax.
- ER\$UBF** Bad address in UBF field Octal: 174520  
Decimal: -1712
- The UBF field of the RAB contains 0 or, for block access, an odd address.
- ER\$UIN** Field value rejected by FAL Octal: 174510  
Decimal: -1720
- The FAL (file access listener) rejected the value in a control block field; the STV field of the FAB or RAB contains a code showing which field. See your DECnet documentation for the meanings of these codes.
- ER\$USZ** Bad value in USZ field Octal: 174500  
Decimal: -1728
- The USZ field of the RAB contains 0.
- ER\$VER** Bad file version number Octal: 174460  
Decimal: -1744
- The file version portion of a file specification contains a syntax error.
- ER\$WCD** Illegal wildcard in merged string Octal: 174430  
Decimal: -1768
- The merged string contains a wildcard character, but wildcarding is not in progress or is illegal for the operation.
- ER\$WER** File processor error Octal: 174420  
Decimal: -1776
- The file processor could not write to the file. The STV field of the FAB or RAB contains the file processor error code; see your operating system documentation for the meaning of the code.
- ER\$WLK** Device write-locked Octal: 174410  
Decimal: -1784
- The device specified is write-locked.
- ER\$WPL** File processor error Octal: 174400  
Decimal: -1792
- The file processor could not write the file prologue. The STV field of the FAB or RAB contains the file processor error code; see your operating system documentation for the meaning of the code.

COMPLETION CODES AND FATAL ERROR CODES

ER\$LIB Resident library not available Octal: 175744  
Decimal: -1052

The version of the RMS-11 resident library needed for your task is not available.

ER\$MAP Error in internal buffer mapping data Octal: 175720  
Decimal: -1072

RMS-11 detected an error in its internal data structures. The error may have been caused by your task writing into the structures; if you think your task did not cause the error, please submit a Software Performance Report to DIGITAL, including the following information:

- Contents of general registers and stack
- Operation and file organization for which the error occurred
- Task builder map of the task

ER\$RAB Bad RAB Octal: 175340  
Decimal: -1312

The value in the BID or BLN field of the specified RAB is not the correct identifier or block length for a RAB, or the address of the RAB is 0 or odd.

**APPENDIX B**  
**ASSEMBLY-TIME MESSAGES**

RMS-11 macros detect some errors during assembly. For each such error, the macro issues a .PRINT or .ERROR assembler directive with a message. This appendix shows these messages and their meanings.

**\$COMPARE MACRO - FIELD TOO LARGE**

You can specify only a 1-byte or 1-word field as the field parameter for the \$COMPARE macro.

**\$COMPARE MACRO - FIELD PARAMETER INVALID**

You must specify a valid field mnemonic as the field parameter for the \$COMPARE macro.

**\$FETCH MACRO - PC DESTINATION INVALID**

You cannot specify the PC as the destination for the \$FETCH macro.

**\$FETCH OR \$STORE MACRO - ADDRESS MODE INVALID**

You have used an illegal address mode in the source for a \$STORE macro or in the destination for a \$FETCH macro. See Chapter 3 for a description of legal address modes for these macros.

**\$FETCH OR \$STORE MACRO - FIELD PARAMETER INVALID**

You can specify only a valid field mnemonic as the field parameter for a field access macro.

**\$FETCH OR \$STORE MACRO - FIELD TOO LARGE FOR GIVEN REGISTERS**

You cannot specify the given register as the source or destination address because the field is larger than the remaining registers.

**\$FETCH OR \$STORE MACRO - FIELD TOO LARGE FOR IMMEDIATE MODE**

You can specify an immediate mode value for a field access macro only if you specify a 1-byte or 1-word field.

**\$FETCH OR \$STORE MACRO - FIELD TOO LARGE FOR REGISTERS**

You cannot specify a register as the source or destination address because the given field is too large.

## ASSEMBLY-TIME MESSAGES

### \$FETCH OR \$STORE MACRO - REGISTER PARAMETER INVALID

You can specify only R0, R1, R2, R3, R4, or R5 as the register parameter for a field access macro.

### \$FETCH OR \$STORE MACRO - REGISTER USAGES OVERLAP

You cannot specify the given register as the source or destination address because the indicated registers overlap the register containing the control block address.

### \$OFF MACRO - FIELD TOO LARGE

You can specify only a 1-byte or 1-word field as the field parameter for the \$OFF macro.

### \$OFF MACRO - FIELD PARAMETER INVALID

You must specify a valid field mnemonic as the field parameter for the \$OFF macro.

### \$SET MACRO - FIELD TOO LARGE

You can specify only a 1-byte or 1-word field as the field parameter for the \$SET macro.

### \$SET MACRO - FIELD PARAMETER INVALID

You must specify a valid field mnemonic as the field parameter for the \$SET macro.

### \$SETGSA MACRO - REGISTER PARAMETER INVALID

You must specify R0, R1, R2, R3, R4, or R5 as the register parameter for the \$SETGSA macro.

### \$TESTBITS MACRO - FIELD TOO LARGE

You can specify only a 1-byte or 1-word field as the field parameter for the \$TESTBITS macro.

### \$TESTBITS MACRO - FIELD PARAMETER INVALID

You must specify a valid field mnemonic as the field parameter for the \$TESTBITS macro.

### F\$BSZ MACRO - BSZ FIELD NOT USED IN RMS-11

RMS-11 has no BSZ field in the FAB; therefore the F\$BSZ macro cannot initialize the field.

### F\$JFN MACRO - JFN FIELD NOT USED IN RMS-11

RMS-11 has no JFN field in the FAB; therefore the F\$JFN macro cannot initialize the field.

### FAB\$B MACRO - ALREADY IN BLOCK OR POOL DECLARATION

You cannot use the FAB\$B macro to begin FAB declaration until you have ended the current block or pool declaration (using the FAB\$E, NAM\$E, POOL\$E, RAB\$E or XAB\$E macro).

### FAB\$B MACRO - FAB NOT WORD-ALIGNED

Use the .EVEN assembler directive before the FAB\$B macro; this assures word-alignment for the FAB.

## FAB\$E MACRO - NOT IN FAB DECLARATION

You must begin a FAB declaration with the FAB\$B macro before ending it with a FAB\$E macro.

## NAM\$B MACRO - ALREADY IN BLOCK OR POOL DECLARATION

You cannot use the NAM\$B macro to begin NAM block declaration until you have ended the current block or pool declaration (using the FAB\$E, NAM\$E, POOL\$E, RAB\$E or XAB\$E macro).

## NAM\$B MACRO - NAM BLOCK NOT WORD-ALIGNED

Use the .EVEN assembler directive before the NAM\$B macro; this assures word-alignment for the NAM.

## NAM\$E MACRO - NOT IN NAM BLOCK DECLARATION

You must begin a NAM block declaration with the NAM\$B macro before ending it with a NAM\$E macro.

## OPERATION MACRO - FAB OR RAB ADDRESS PARAMETER MISSING

You must specify a control block address for the operation macro; for a file operation, specify a FAB address; for a stream, record, or block I/O operation, specify a RAB address.

## ORG\$ MACRO - OPERATION PARAMETER INVALID

You can specify only CRE, DEL, FIN, GET, PUT, and UPD as operation parameters for the ORG\$ macro.

## ORG\$ MACRO - ORGANIZATION PARAMETER INVALID

You can specify only IDX, REL, or SEQ as the organization parameter for the ORG\$ macro.

## ORG\$ MACRO - ORGANIZATION PARAMETER MISSING

You must specify IDX, REL, or SEQ as the organization parameter for the ORG\$ macro.

## POOL\$B MACRO - ALREADY IN BLOCK OR POOL DECLARATION

You cannot use the POOL\$B macro to begin pool declaration until you have ended the current block or pool declaration (using the FAB\$E, NAM\$E, POOL\$E, RAB\$E or XAB\$E macro).

## POOL\$E MACRO - NOT IN POOL DECLARATION

You must begin a POOL declaration with the POOL\$B macro before ending it with a POOL\$E macro.

## R\$LSN MACRO - LSN FIELD NOT USED IN RMS-11

RMS-11 has no LSN field in the RAB; therefore the R\$LSN macro cannot initialize the field.

## RAB\$B MACRO - ALREADY IN BLOCK OR POOL DECLARATION

You cannot use the RAB\$B macro to begin RAB declaration until you have ended the current block or pool declaration (using the FAB\$E, NAM\$E, POOL\$E, RAB\$E or XAB\$E macro).

## ASSEMBLY-TIME MESSAGES

### RAB\$B MACRO - RAB NOT WORD-ALIGNED

Use the .EVEN assembler directive before the RAB\$B macro; this assures word-alignment for the RAB.

### RAB\$B MACRO - RAB TYPE PARAMETER INVALID

You can specify only SYN, ASYN, or a null as the parameter for the RAB\$B macro.

### RAB\$E MACRO - NOT IN RAB DECLARATION

You must begin a RAB declaration with the RAB\$B macro before ending it with a RAB\$E macro.

### X\$SIZ MACRO - TOTAL KEY SIZE TOO LARGE

The sum of the segment sizes for a key is greater than 255. Specify smaller segments.

### XAB\$B MACRO - ALREADY IN BLOCK OR POOL DECLARATION

You cannot use the XAB\$B macro to begin XAB declaration until you have ended the current block or pool declaration (using the FAB\$E, NAM\$E, POOL\$E, RAB\$E or XAB\$E macro).

### XAB\$B MACRO - XAB NOT WORD-ALIGNED

Use the .EVEN assembler directive before the XAB\$B macro; this assures word-alignment for the XAB.

### XAB\$B MACRO - XAB TYPE PARAMETER INVALID

You can specify only XB\$ALL, XB\$DAT, XB\$KEY, XB\$PRO, or XB\$SUM as the XAB type parameter for the XAB\$B macro.

### XAB\$E MACRO - NOT IN XAB DECLARATION

You must begin a XAB declaration with the XAB\$B macro before ending it with a XAB\$E macro.

## APPENDIX C

### MACROS THAT DECLARE SYMBOLS AND OTHER MACROS

Table C-1 lists RMS-11 macros (and their arguments) that declare symbols and other macros. In the table, the expression **xxx** represents a 2- or 3-character string, so that the expression **O\$xxx** represents all symbols that begin with **O\$**; the expression **fld** represents a field mnemonic.

Note that you can declare symbols either globally or locally. For a **FAB\$BT**, **RAB\$BT**, **XAB\$BT**, or **\$RMSTAT** macro, give the argument **DFIN\$G** (or omit the argument) to define symbols globally; give the argument **DFIN\$L** to define symbols locally.

Note also that you can declare symbols for control block sizes without declaring field-offset symbols. For a **FABOF\$**, **NAMOF\$**, **RABOF\$**, **XABOF\$**, **XBAOF\$**, **XBDOF\$**, **XBKOF\$**, **XBPOF\$**, or **XBSOF\$** macro, give the argument **DEF\$SZ** to define only symbols for block sizes, or give no argument to define both symbols for block sizes and field-offset symbols.

**Table C-1: Macros That Declare Symbols and Other Macros**

Macro	Argument	Declares
<b>FAB\$B</b>		<ul style="list-style-type: none"> <li>- FAB field-initialization macros: of the form <b>F\$fld</b></li> <li>- FAB end-block-declaration macro: <b>FAB\$E</b></li> <li>- FAB field-offset symbols: of the form <b>O\$fld</b></li> <li>- FAB code and mask symbols: of the form <b>FB\$xxx</b></li> </ul>
<b>FAB\$BT</b>	<b>DFIN\$G</b>	- Global FAB code and mask symbols: of the form <b>FB\$xxx</b> (except FAB length symbol <b>FB\$BLN</b> )
<b>FAB\$BT</b>	<b>DFIN\$L</b>	- Local FAB code and mask symbols: of the form <b>FB\$xxx</b> (except FAB length symbol <b>FB\$BLN</b> )
<b>FABOF\$</b>		<ul style="list-style-type: none"> <li>- FAB field offset symbols: of the form <b>O\$fld</b></li> <li>- FAB length symbol: <b>FB\$BLN</b></li> </ul>
<b>FABOF\$</b>	<b>DEF\$SZ</b>	- FAB length symbol: <b>FB\$BLN</b>

(Continued on next page)

MACROS THAT DECLARE SYMBOLS AND OTHER MACROS

Table C-1 (Cont.): Macros That Declare Symbols and Other Macros

Macro	Argument	Declares
\$FBCAL		- Directory operation macros: \$PARSE, \$RENAME, and \$SEARCH - File operation macros: \$CLOSE, \$CREATE, \$DISPLAY, \$ERASE, \$EXTEND, and \$OPEN
\$GNCAL		- Get-space address macros: GSA\$, \$GETGSA, and \$SETGSA - Facilities-declaration macro: ORG\$ - RMS-11 initialization macros: \$INIT and \$INITIF (obsolete) - Field-access macros: \$COMPARE, \$FETCH, \$OFF, \$SET, \$STORE, and \$TESTBITS - Completion-handler return macro: \$RETURN
NAM\$B		- NAM block field-initialization macros: of the form N\$fld - NAM block end-block-declaration macro: NAM\$E - NAM block field-offset symbols: of the form O\$fld - NAM block code and mask symbols: of the form NB\$xxx
NAMOF\$		- NAM block field offset symbols: of the form O\$fld - NAM block length symbol: NB\$BLN
NAMOF\$	DEF\$SZ	- NAM block length symbol: NB\$BLN
POOL\$B		- Pool declaration macros: P\$BDB, P\$BUF, P\$FAB, P\$IDX, P\$RAB, and P\$RABX - End-pool-declaration macro: POOL\$E
RAB\$B		- RAB field-initialization macros: of the form R\$fld - RAB end-block-declaration macro: RAB\$E - RAB field-offset symbols: of the form O\$fld - RAB code and mask symbols: of the form RB\$xxx
RAB\$BT	DFIN\$G	- Global RAB code and mask symbols: of the form RB\$xxx (except RAB length symbol RB\$BLN)
RAB\$BT	DFIN\$L	- Local RAB code and mask symbols: of the form RB\$xxx (except RAB length symbol RB\$BLN)
RABOF\$		- RAB field offset symbols: of the form O\$fld - RAB length symbol: RB\$BLN
RABOF\$	DEF\$SZ	- RAB length symbol: RB\$BLN

(Continued on next page)

Table C-1 (Cont.): Macros That Declare Symbols and Other Macros

Macro	Argument	Declares
\$RBCAL		<ul style="list-style-type: none"> <li>- Stream operation macros: \$CONNECT, \$DISCONNECT, \$FLUSH, \$FREE, \$NXTVOL, \$REWIND, and \$WAIT</li> <li>- Record operation macros: \$DELETE, \$FIND, \$GET, \$PUT, \$TRUNCATE, and \$UPDATE</li> <li>- Block operation macros: \$READ, \$SPACE, and \$WRITE</li> </ul>
\$RMSTAT	DFIN\$G	- Global completion symbols: of the forms ER\$xxx and SU\$xxx
\$RMSTAT	DFIN\$L	- Local completion symbols: of the forms ER\$xxx and SU\$xxx
XAB\$B	XB\$ALL	<ul style="list-style-type: none"> <li>- ALL block field-initialization macros: of the form X\$fld</li> <li>- XAB end-block-declaration macro: XAB\$E</li> <li>- ALL block field-offset symbols: of the form O\$fld</li> <li>- XAB code and mask symbols: of the form XB\$xxx</li> </ul>
XAB\$B	XB\$DAT	<ul style="list-style-type: none"> <li>- DAT block field-initialization macros: of the form X\$fld</li> <li>- XAB end-block-declaration macro: XAB\$E</li> <li>- DAT block field-offset symbols: of the form O\$fld</li> <li>- XAB code and mask symbols: of the form XB\$xxx</li> </ul>
XAB\$B	XB\$KEY	<ul style="list-style-type: none"> <li>- KEY block field-initialization macros: of the form X\$fld</li> <li>- XAB end-block-declaration macro: XAB\$E</li> <li>- KEY block field-offset symbols: of the form O\$fld</li> <li>- XAB code and mask symbols: of the form XB\$xxx</li> </ul>
XAB\$B	XB\$PRO	<ul style="list-style-type: none"> <li>- PRO block field-initialization macros: of the form X\$fld</li> <li>- XAB end-block-declaration macro: XAB\$E</li> <li>- PRO block field-offset symbols: of the form O\$fld</li> <li>- XAB code and mask symbols: of the form XB\$xxx</li> </ul>
XAB\$B	XB\$SUM	<ul style="list-style-type: none"> <li>- SUM block field-initialization macros: of the form X\$fld</li> <li>- XAB end-block-declaration macro: XAB\$E</li> <li>- SUM block field-offset symbols: of the form O\$fld</li> <li>- XAB code and mask symbols: of the form XB\$xxx</li> </ul>

(Continued on next page)

MACROS THAT DECLARE SYMBOLS AND OTHER MACROS

Table C-1 (Cont.): Macros That Declare Symbols and Other Macros

Macro	Argument	Declares
XAB\$BT	DFIN\$G	- Global XAB code and mask symbols: of the form XB\$xxx (except XAB length symbols: XB\$LAL, XB\$DTL, XB\$KYL, XB\$PRL, and XB\$SML)
XAB\$BT	DFIN\$L	- Local XAB code and mask symbols: of the form XB\$xxx (except XAB length symbols: XB\$LAL, XB\$DTL, XB\$KYL, XB\$PRL, and XB\$SML)
XABOF\$		- XAB field offset symbols: of the form O\$fld - XAB length symbols: XB\$LAL, XB\$DTL, XB\$KYL, XB\$PRL, and XB\$SML
XABOF\$	DEF\$SZ	- XAB length symbols: XB\$LAL, XB\$DTL, XB\$KYL, XB\$PRL, and XB\$SML
XBAOF\$		- ALL block field offset symbols: of the form O\$fld - ALL block length symbol: XB\$LAL
XBAOF\$	DEF\$SZ	- ALL block length symbol: XB\$LAL
XBDOF\$		- DAT block field offset symbols: of the form O\$fld - DAT block length symbol: XB\$DTL
XBDOF\$	DEF\$SZ	- DAT block length symbol: XB\$DTL
XBKOF\$		- KEY block field offset symbols: of the form O\$fld - KEY block length symbol: XB\$KYL
XBKOF\$	DEF\$SZ	- KEY block length symbol: XB\$KYL
XBPOF\$		- PRO block field offset symbols: of the form O\$fld - PRO block length symbol: XB\$PRL
XBPOF\$	DEF\$SZ	- PRO block length symbol: XB\$PRL
XBSOF\$		- SUM block field offset symbols: of the form O\$fld - SUM block length symbol: XB\$SML
XBSOF\$	DEF\$SZ	- SUM block length symbol: XB\$SML

## APPENDIX D

### RMS-11 WITH DIFFERENT OPERATING SYSTEMS

This appendix contrasts the behaviors of RMS-11 on different operating systems:

- PRO/RMS-11 versus RSTS/E RMS-11
- PRO/RMS-11 versus RSX-11M/M-PLUS RMS-11
- RSTS/E RMS-11 versus RSX-11M/MPLUS RMS-11

#### D.1 PRO/RMS-11 VERSUS RSTS/E RMS-11

This section contrasts the behaviors of PRO/RMS-11 and RSTS/E RMS-11.

##### D.1.1 Different Behaviors

The following features behave differently for RSTS/E and P/OS users:

- **Macro library location**

RMS-11 macro libraries for the systems are located in the files:

RSTS/E	LB:RMSMAC.MLB
P/OS	LB:[1,1]RMSMAC.MLB

- **RTV field in FAB**

The RTV field in the FAB has different uses:

RSTS/E	Cluster size
P/OS	Retrieval pointer count

- **Maximum bucket size**

The maximum bucket sizes (given by the BKS field in the FAB or the BKZ fields in ALL blocks) are different:

RSTS/E	15 blocks
P/OS	32 blocks

## RMS-11 WITH DIFFERENT OPERATING SYSTEMS

- **Area alignment**

The meanings of area alignment codes (in the ALN field of an ALL block) are different:

RSTS/E	XB\$LBN	Cluster alignment
P/OS	XB\$CYL	Cylinder alignment
	XB\$LBN	Logical block alignment
	XB\$VBN	Virtual block alignment

- **Protection codes**

The protection codes (and defaults) are system-specific.

### D.1.2 Features Not Supported on RSTS/E

The following RMS-11 features are not supported on RSTS/E, but are supported on P/OS:

- ENTER operation (\$ENTER macro)
- NXTVOL operation (\$NXTVOL macro)
- REMOVE operation (\$REMOVE macro)
- SPACE operation (\$SPACE macro)
- WAIT operation (\$WAIT macro)
- User-provided interlocking (FB\$UPI mask in SHR field of FAB)
- File version numbers (NB\$VER mask in FNB field of NAM)
- Asynchronous execution of operations (RB\$ASY mask in ROP field of RAB; SYN and ASYN arguments to RAB\$B macro; RB\$BLL symbol for length of asynchronous RAB)
- Directories (DID field in NAM block)
- Area extension (ALL block fields for \$EXTEND macro)
- Contiguous file extension (FB\$CTG mask in FOP field of FAB for \$EXTEND macro)
- Hard placement (XB\$HRD mask in AOP field of ALL block)
- Return of date and protection information by DISPLAY operation (PRO block fields and DAT block fields for \$DISPLAY macro)
- File expiration date (EDT field of NAM block) and file revision number (RVN field of NAM block)

### D.1.3 Features Not Supported on P/OS

On RSTS/E, for compatibility with older file system, RMS-11 treats certain sequential files with undefined records as sequential files with stream records. P/OS will allow only block access to such files. In addition, magtape devices are not supported on P/OS, and remote operations are not supported on P/OS.

## D.2 PRO/RMS-11 VERSUS RSX-11M/M-PLUS RMS-11

The P/OS operating system does not support magtape devices or remote RMS-11 operations.

P/OS files have decimal version numbers (NB\$VER mask in FNB field of NAM).

## D.3 RSTS/E RMS-11 VERSUS RSX-11M/M-PLUS RMS-11

This section contrasts the behaviors of RSTS/E RMS-11 and RSX-11M/M-PLUS RMS-11.

## D.3.1 Different Behaviors

The following features behave differently for RSTS/E and RSX-11M/M-PLUS users:

- Macro library location

RMS-11 macro libraries for the systems are located in the files:

RSTS/E	LB:RMSMAC.MLB
RSX-11M/M-PLUS	LB:[1,1]RMSMAC.MLB

- RTV field in FAB

The RTV field in the FAB has different uses:

RSTS/E	Cluster size
RSX-11M/M-PLUS	Retrieval pointer count

- Maximum bucket size

The maximum bucket sizes (given by the BKS field in the FAB or the BKZ fields in ALL blocks) are different:

RSTS/E	15 blocks
RSX-11M/M-PLUS	32 blocks

- Area alignment

The meanings of area alignment codes (in the ALN field of an ALL block) are different:

RSTS/E	XB\$LBN	Cluster alignment
RSX-11M/M-PLUS	XB\$CYL	Cylinder alignment
	XB\$LBN	Logical block alignment
	XB\$VBN	Virtual block alignment

D.3.2 Features Not Supported on RSTS/E

The following RMS-11 features are not supported on RSTS/E, but are supported on RSX-11M/M-PLUS:

- ENTER operation (\$ENTER macro)
- NXTVOL operation (\$NXTVOL macro)
- REMOVE operation (\$REMOVE macro)
- REWIND operation for magtape device (\$REWIND macro)
- SPACE operation (\$SPACE macro)
- WAIT operation (\$WAIT macro)
- User-provided interlocking (FB\$UPI mask in SHR field of FAB)
- Octal file version numbers (NB\$VER mask in FNB field of NAM)
- Asynchronous execution of operations (RB\$ASY mask in ROP field of RAB; SYN and ASYN arguments to RAB\$B macro; RB\$BLL symbol for length of asynchronous RAB)
- Directories (DID field in NAM block)
- Area extension (ALL block fields for \$EXTEND macro)
- Contiguous file extension (FB\$CTG mask in FOP field of FAB for \$EXTEND macro)
- Hard placement (XB\$HRD mask in AOP field of ALL block)
- Return of date and protection information by DISPLAY operation (PRO block fields and DAT block fields for \$DISPLAY macro)
- File expiration date (EDT field in NAM block) and file revision number (RVN field of NAM block)
- Initial end-of-file context for magtape file (FB\$NEF mask in FOP field of FAB for \$OPEN macro)
- Multivolume magtapes

## INDEX

- \$CLOSE macro, 5-3
  - \$COMPARE macro, 2-16
    - example, 7-3, 7-7, 7-11, 7-15
  - \$CONNECT macro, 5-5
  - \$CREATE macro, 5-8
  - \$DELETE macro, 5-24
  - \$DISCONNECT macro, 5-26
  - \$DISPLAY macro, 5-28
    - P/OS, D-2
    - RSX-11, D-4
  - \$ENTER macro
    - P/OS, D-2
    - RSX-11, D-4
  - \$ERASE macro, 5-33
    - example, 7-11
  - \$EXTEND macro, 5-38
    - P/OS, D-2
    - RSX-11, D-4
  - \$FBCAL macro, C-2
  - \$FETCH macro, 2-15
    - example, 7-3, 7-7, 7-11, 7-15
  - \$FIND macro
