

1. IDENTIFICATION
- 1.1 PDP-8 Maindec 826-A
- 1.2 680 8-Bit Character Exerciser
- 1.3 November 8, 1965

## 2. ABSTRACT

The 680 8-Bit Character Exerciser program further verifies correct operation of the 680 DCS system. This test assumes that the Teletype lines are full duplex. However, if the line outputs are jumpered to the line inputs, the test does verify that the input characters are received as transmitted.

## 3. REQUIREMENTS

### 3.1 Storage

#### 3.1.1 Exerciser Program

	ADDRESS	0	
Concurrent Output Test	1200 <sub>8</sub>	to	1377 <sub>8</sub>
Output Data Table	1400 <sub>8</sub>	to	1535 <sub>8</sub>
Concurrent Input Test	1600 <sub>8</sub>	to	1616 <sub>8</sub>
Output Switch Register Routine	2000 <sub>8</sub>	to	2074 <sub>8</sub>
Output Buffer	2200	to	2377 <sub>8</sub>
Input Buffer	2400	to	2577 <sub>8</sub>
Interrupt Routine	0001	to	0004

#### 3.1.2 Character Assembly Subroutines (List of Items)

TT8BGN (Start of Subroutines)	3000 <sub>8</sub>	to	3376 <sub>8</sub>
T8IN (TTI Area)	3377 <sub>8</sub>	to	4177 <sub>8</sub>
T8IBF (Input Buffer)	4200 <sub>8</sub>	to	4577 <sub>8</sub>
T80BF (Output Buffer)	4600 <sub>8</sub>	to	4777 <sub>8</sub>
T80BF2 (Second Output Buffer)	5000 <sub>8</sub>	to	5177 <sub>8</sub>
TT8PG0 (Page 0 Constants)	0126 <sub>8</sub>	to	0144 <sub>8</sub>
TTCHAR (Character Register)	0177 <sub>8</sub>		
T8AX1 (Autoindex)	14		
T8AX2 (Autoindex)	15		
T8AX3 (Autoindex)	16		

### 3.2 Subprograms and/or Subroutines

Digital-8-35-S-B, 680 8-Bit Character Assembly Subroutines

### 3.3 Equipment

Minimum Configuration PDP-8  
680 DCS hardware (including a 110 Baud Clock)

### 3.4 Miscellaneous

The 110 Baud Clock in CLOCK 2.

#### 4. USAGE

##### 4.1 Loading

4.1.1 If the Binary Loader beginning at address 7777 is in memory, see Section 4.1.2. Otherwise the RIM Loader and/or the Binary Loader must be loaded into memory.

4.1.2 The 680 8-Bit Character Exerciser may now be loaded into memory as follows:

Set 7777<sub>8</sub> in the SWITCH REGISTER  
Press the LOAD ADDRESS key  
Place the Character Exerciser in the keyboard reader  
Press START  
Engage the keyboard reader

##### 4.3 Switch Settings (See Section 4.4)

##### 4.4 Start up and/or Entry

##### 4.4.1 Concurrent Output Test

Set the SWITCH REGISTER to 1200

Press the LOAD ADDRESS key.

Set the SWITCH REGISTER equal to the lowest line number to be tested.

Press START; the processor halts at address 1202.

Set the SWITCH REGISTER equal to the number of lines to be tested. *works OK for 2 lines*

Press CONTINUE; the program outputs a fixed message on all the lines selected. *higher no. not tested.*

##### 4.4.2 Concurrent Input Test

Set the SWITCH REGISTER to 1600.

Press the LOAD ADDRESS key.

Press START; the program scans 128 lines for input and retransmits characters received on the same line as they are received. *Response to keyboard may slow or not prevent. Reducing no. of lines as below, works OK. Response slows down as no. of lines increases.*

Note that the 680 8-Bit Character Assembly subroutines as currently coded will not process 128 lines at 110 Baud. Therefore, it is necessary to do the following before running the Concurrent Input Test:

Set the SWITCH REGISTER to 1616. *✓*

Press the LOAD ADDRESS key.

Set the SWITCH REGISTER equal to the number of lines on the system.

Press the DEPOSIT key.

The Concurrent Input Test may be run as above.

##### 4.4.3 Output the contents of the SWITCH REGISTER.

Set the SWITCH REGISTER to 2000.

Press the LOAD ADDRESS key.

Set the SWITCH REGISTER to the line number to be tested.

Press START; the processor halts at address 2002.

Set SWITCH REGISTER bits 4 through 11 equal to the character to be transmitted, and SW0 as follows:

SW0 - down: Do not test for input.

SW0 - up: Wait for input and verify that it is the same character as transmitted.

Press CONTINUE; the program transmits a carriage return, line feed, the contents of the AC switches 64 times, and then repeats.

Note that since the input is two characters behind the output, (due to the double buffering of the Character Assembly Subroutines), SW0 may not be changed from 0 to a 1 once the program is running. It may, however, be changed from a 1 to a 0 and switches 4 through 11 may be altered at any time.

#### 4.5 Errors In Usage

Hardware malfunctions detected by the program result in a processor halt. The following is a list of these error halts and their meanings:

##### 4.5.1 Address 0002 Not Clock Interrupt

Either an interrupt was received from a device other than Teletype Clock 2 or the IOT 6431 did not skip after an interrupt from Clock 2.

##### 4.5.2 Address 1312 Data Error

The processor halts with a line number displayed in the AC, indicating that a data error has occurred on that line. Press CONTINUE and the processor halts at address 1315 with the character that should have been received in the AC. Press CONTINUE again and the processor halts with the character that is received in the AC.

##### 4.5.3 Address 2060 Data Error (Output AC Switches Routine)

Processor halts with the character transmitted in the AC. This could be a carriage return, a line feed, or the code contained in the SWITCH REGISTER. Press CONTINUE, and the processor halts with the character that is displayed in the AC.

##### 4.5.4 Detection of an Open Input Line.

If the data error halt at address 1312 is consistently executed with a specific line number and the character received is always 0, it indicates that the input line is in a constant "SPACE" or open line state.

##### 4.5.5 Detection of a Constant "MARK"

The 680 Character Exerciser was written with the assumption that the Teletype lines being tested are full duplex. Also, the program assumes that any input received during the Concurrent Output Test is due to the fact that the line outputs are tied to line inputs. Therefore, if there is no input on a line or any of the lines, the program does not consider it an error. Assuming the test is operating with inputs tied to outputs, the only way to be sure that a line is transmitting and receiving is to open the input line in order to force a data error.

Note that this procedure is also likely to display any errors in translating line numbers; i.e., input line 17 is opened and the processor does not halt. The line is then closed again and an error is indicated on line 37. The malfunction is probably in the decoding of line 17.

#### 4.6 Recovery from Such Errors

Pressing CONTINUE causes the program to proceed. It is possible that an error halt will leave some of the output lines in a "SPACE" condition. If this happens, any Teletypes that are tied to these outputs will run freely until the program continues. Also, in the process of opening lines to test for transmitting and receiving, it is possible to get the input of a line out of sequence with the output. In this case, it is necessary that the test be restarted.

#### 5. Restrictions

The Character Assembly Subroutines scan the lines in even multiples of eight lines. Therefore, it is possible that an error could be indicated on a line or lines that have not been selected to be run, i.e., the Output SWITCH REGISTER Routine, if line 1 is selected to be run, the inputs of lines 2, 3, 4, 5, 6, 7 and 10<sub>8</sub> should be placed in the "MARK" state.

#### 6. DESCRIPTION

##### 6.1 Discussion

##### 6.1.1 General

The 680 8-Bit Character Exerciser transmits and/or receives ASCII Teletype data at the line speed of Teletype clock 2 and verifies correct operation of the 680 DCS hardware. The program allows parameters to exercise up to 128 lines and includes three modes of test: Concurrent Output, Concurrent Input, and Output the Switch Register.

##### 6.1.2 Test Descriptions

##### 6.1.2.1 Concurrent Output Test

The Concurrent Output Test will accept parameters to transmit on from 1 to 128 lines. The program assumes that all of the lines selected are full duplex and that any input is due to an output line jumpered to an input line. The following message is transmitted on all lines selected:

```
THE QUICK BROWN FOX JUMPED OVER THE LAZY DOG'S BACK
0123456789 : " # $ % ' ( ) * + - . / : ; < = > ? @ [ \ ] ^ _
```

If input is received on any of the lines selected, the program verifies that the characters received are received in the same order that they are transmitted. Also, since the input is tested almost independently of the output, it is possible to jumper input lines to output lines in any configuration that is desired, including and/or other than 1 for 1.

##### 6.1.2.2 Concurrent Input Test

The Concurrent Input Test initializes to scan all 128 lines for input. When a character is received on a line, the program transmits the character received on the same line. (See Section 4.4.2.)

##### 6.1.2.3 Output the Switch Register Routine

This routine transmits the code contained in SWITCH REGISTER bits 4 through 11 on the line specified by the contents of the SWITCH REGISTER when the routine is started. The program transmits a carriage return, line feed, the contents of the SWITCH REGISTER 64 times, and then repeats. If SWITCH REGISTER bit 0 is a 1, the program transmits a character, waits for it to be input, and then verifies that the output and the input are equal. Since the input is two characters behind the output, (due to the double buffering of output characters in the Character Assembly Subroutines) the compare mode must be selected at the time the processor halts at address 2003.
